Using Computer-aided Argument Mapping to Teach Reasoning

Martin Davies, Ashley Barnett, and Tim van Gelder

1. Introduction¹

Argument mapping is a way of diagramming the logical structure of an argument to explicitly and concisely represent reasoning. (See Figure 1, for an example.) The use of argument mapping in critical thinking instruction has increased dramatically in recent decades. A brief history of argument mapping is provided at the end of this chapter.

Pre- and post-test studies have demonstrated the pedagogical benefit of argument mapping using cohorts of university students and intelligence analysts as subjects, and by comparing argument mapping interventions with data from comparison groups or benchmarks from other meta-analytic reviews. It has been found that intensive practice mapping arguments with the aid of software has a strong positive effect on the critical thinking ability of students. Meta-analysis has shown that high-intensity argument mapping courses improve critical thinking scores by around 0.8 of a standard deviation—more than twice the typical effect size for standard critical thinking courses (van Gelder, 2015). This strongly suggests that argument mapping is a very effective way to teach critical thinking.

The process of making an argument map is beneficial because it encourages students to construct (or reconstruct) their arguments with a level of clarity and rigor that, when divorced from prose, often goes unnoticed. The shortcomings of a badly-constructed map are plain to see. This is not the case with dense blocks of written prose, which can give an impressionistic sense of rigor to the reader.

¹ The colored versions of the argument maps in this chapter are available only in the open-access Ebook edition of this book at: <https://windsor.scholarsportal.info/omp/index.php/wsia/catalog>

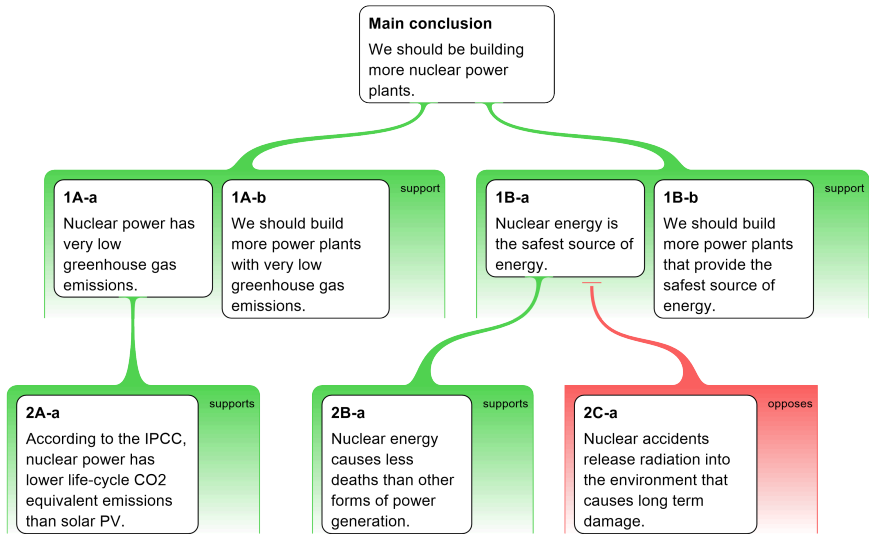

Figure 1. A short argument showing the main conventions used in argument mapping. The main conclusion is placed at the top of the map. The reasons for the main conclusion are identified by green shaded areas connected by lines to the main conclusion. The main conclusion in this example has two reasons, 1A and 1B. Inside the green shaded areas white claim boxes are used to display individual premises. Premises are placed in separate premise boxes because each premise needs its own justification. The surrounding green reason envelope effectively groups together linked premises working together to form a reason for the conclusion. Argument maps clearly show which premises of a reason are supported by further reasoning. For example, 1A-a is a premise, which is itself supported by a reason, 2A-a. As claim 1A-a is both a premise in one inference and a conclusion in another it sometimes called an ‘intermediate conclusion’ or lemma. Objections to claims are identified by a red shaded area. In the map above, there is only one objection, 2C-a. NB: When colour cannot be used, the labels to the right of the shading helps to designate reasons and objections (i.e., the words ‘supports’, ‘opposes’).

Argument maps can also help students evaluate reasoning because they can easily focus on evaluating each inferential step of an argument. These inferential steps are indicated by the green and red connecting lines in the example provided. Students using argument mapping software can easily see how their evaluation of each step affects the conclusion. For example, in the argument in Figure 1, suppose the objection in red is strong enough that we can no longer accept claim 1B-a in the reason above it. That would mean that the second reason given for the contention (formed by claims 1B-a and 1B-b) no longer offers any support for the conclusion. However, the first reason (formed by claims 1A-a and 1A-b) is unaffected by the objection and may still be strong enough to establish the conclusion. A map makes this very intu-

itive. It is much harder to see the implications of changing premises using prose alone and without the visual markers provided by mapping software.

One of the main pitfalls when using argument mapping in teaching is that students may find the level of rigor and clarity encouraged by the technique to be onerous. However, using interesting examples that increase the demands of the argument mapping course gradually and incrementally allows students to have fun exploring how different arguments work. In most argument mapping software students can freely move the parts of an argument around and experiment with different logical structures. This ability to “play around” with an argument allows students, over time, to gain a deep and practiced understanding of the structure of arguments—an important aim of any critical thinking course. Anecdotally, it also helps with student engagement: by manipulating parts of a map using a software, participants more actively engage with critical thinking tasks than they would do otherwise (i.e., if maps were not being used).

From an instructor’s point of view, adapting a classroom to teach critical thinking using argument mapping requires flexibility, and a willingness to experiment and try out new methodologies and principles. Some of these are covered in this paper. Fortunately, a variety of software and the exercises needed to run an argument mapping course are available for free online. We return to these later.

2. Computer-aided argument mapping

Computer-aided argument mapping (CAAM) uses software programs specifically designed to allow students to quickly represent reasoning using box and line diagrams. This can, in principle, be done without software (Harrell, 2008), but the software makes it much easier. Boxes are used to contain claims and lines are used to show which claims are reasons for others. The software does not itself *analyze* argumentative texts, or check the validity of the arguments, but by making argument maps students can, with practice, get better at argument analysis and evaluation.

In terms of entry-level skills required to use CAAM, little more is needed other than a solid understanding of the target language, basic computer skills, a broad familiarity with the importance of critical thinking, and a willingness to experiment with argument mapping software. In terms of achieving *expertise* in using CAAM, however, a rigorous approach to text analysis is involved, along with adoption of a number of CAAM methodical principles, and of course, the help of a dedicated and experienced instructor. Lots of argument mapping practice (LAMP) is also recommended (Rider and Thomason, 2008).

The theoretical basis for argument mapping *improving* critical thinking skills is based on two principles:

1. It takes for granted the well-established notion of dual coding as it is understood in cognitive science. Human information processing is enhanced by the use of a number of sensory modalities. Diagrams and words allow better cognitive processing of complex information than words alone.
2. It assumes the not unreasonable point that cognitive processing capacity in humans is limited, and that understanding complex arguments is enhanced by “off-loading” information as visual displays (in other words, it’s easier to remember and understand information if one can draw a diagram).

Argument mapping is similar to other mapping tools such as mind mapping and concept mapping. All attempt to represent complex relationships. However, there are also important differences. Unlike mind mapping, which is concerned with associational relationships between ideas, and concept mapping, which is concerned with relational connections between statements and events, argument mapping is principally concerned with inferential or logical relationships between claims (Davies, 2011). There is a difference between argument mapping and various diagrammatic representations in formal logic too. Argument mapping is concerned with representing informal, i.e., “real world”, or natural language argumentation. It thus contrasts with the use of diagrammatic techniques such as Venn diagrams as used in formal logic. In an important sense, argument maps should make intelligible what is going on in arguments as they are (imperfectly) expressed in prose.

As noted, argument mapping software provides several benefits in the classroom. The software makes building argument maps easy, so teachers can provide their students with many practical exercises to work on. Because the software allows the students to edit their maps freely, they can engage in self-directed exploratory learning as they try out different argument structures to see what works best.

Argument maps also show the anatomy of an argument more clearly than can be done in prose. By seeing models of well-constructed maps, students can appreciate how all arguments are made up of claims and how some of these work together as co-premises. They can see at a glance how claims belong to separate lines of reasoning, and can see why some claims are necessary for an argument to succeed and why some are not.

For example, often when students are presented with a range of reasons for a conclusion in prose, they will focus on counting the mistakes and erro-

neously think that the side of the debate that made the most number of outrageous mistakes must be wrong about the conclusion. But by presenting the argument in the form of a map illustrates the point that these bad reasons neither increase or decrease the reliability of a conclusion, and hence are irrelevant to our final evaluation. Instead, attention needs to be focused on the strongest reasons, not the number. It is possible that the side of an argument that presented the worst reasons for a given conclusion also provided the most conclusive reason (see Figure 2).

Argument maps can make discussing complicated arguments in a classroom much easier too. The number of reasons or objections to a contention can be easily “read-off” an argument map (this is difficult to do with a prose equivalent). Example arguments can be displayed on the projector and the teacher can point precisely to the part of the argument that he or she wants to discuss. When debating issues in a classroom, using argument maps can help externalize and depersonalize the debate so that the students are no longer arguing with one another in a competitive way but are collaborating on mapping an argument together in an attempt to construct the best argument for or against the conclusion. This promotes a sense of involvement in a joint scholarly enterprise.

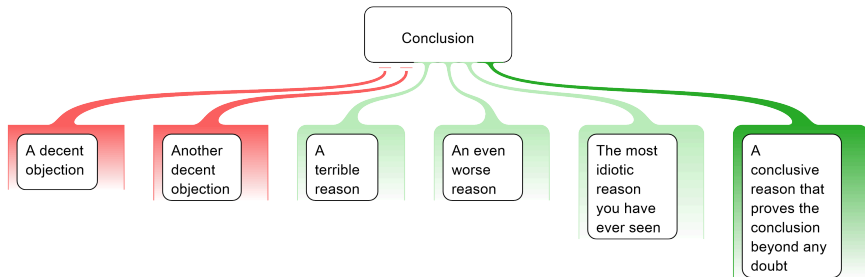

Figure 2. Argument maps clearly distinguish between separate reasons, so it easier to focus on the logical implications of the good reasons and not get distracted by the bad reasons that should just be ignored when it comes to evaluating the conclusion.

An additional benefit is this: Maps also make assessing student’s reasoning skills much easier in assignments, because the teacher can clearly see what his or her students had in mind without the confounding variables to be found in an argumentative essay (Davies, 2009). Also, asking the students to make an argument map prior to writing an argumentative essay can also help ensure that the basic structure of the argument is adequate before they start writing. For a number of reasons, this can assist in the process of essay writing.

3. Teaching using computer-aided argument mapping

Let us now look at how to teach critical thinking using argument mapping. Some of these points apply to any informal logic or critical thinking class, but they are particularly relevant to any class intending to use argument mapping as a teaching tool.

3.1 *The parts of an argument*

In teaching students about argument mapping it is helpful to first distinguish the following component parts of an argument and to provide examples of each:

- *Contention/conclusion* (a singular claim being argued for);
- *Reasons* (a set of claims working together to support a conclusion or sub-conclusion);
- *Objections* (a claim, or set of claims working together to oppose or undermine a conclusion, another reason, or an inference);
- *Inference* (a logical move or progression from reasons to contention);
- *Inference indicator words* (a word or phrase that identifies a logical progression from reasons to a contention, such as ‘because’, ‘therefore’ or ‘it can be concluded that’);
- *Evidential sources taken as the endpoint of a line of reasoning* (arguments must end somewhere, and often this will be a source of information, e.g., a media report, or an expert opinion, that we expect people to accept without the need for additional argument).

3.1.1 *Claims*

Argument mapping concerns itself with relationships between claims or propositions. The first main challenge is to discuss with students the nature of claims. Experience in teaching argument mapping has shown us that students find this concept problematic, and, if students are unclear about claims, they cannot easily create argument maps.

How can the notion of a claim be taught to students? One might start with definitions such as:

- *A claim is a declarative sentence that has a truth value; or*
- *A claim is an assertion that can be agreed with or disagreed with (or partly agreed with).*

Often, however, students find such definitions difficult to grasp. It is best to start with examples of simple empirical statements using the first definition above. Model claims can be instructive here, along with a discussion about the states of affairs that can establish if and whether certain sentences can be said to be true or false (or empirically uncertain):

- *The door is shut.* (This might be true, false, or empirically unclear, i.e., when viewed from an angle).
- *Donald Trump was elected President of the United States.* (This is clearly true, and there are a number of facts that make it so.)
- *Sally is at McDonald's.* (This could be determined by observational evidence and perhaps knowledge of Sally dining habits.)
- *Acid turns blue litmus paper red.* (This could be determined by various procedures used in the science of Chemistry.)

Students should then be encouraged to find similar claims in published literature. They should practice reading passages from texts, paying attention to whether the claims meet the standard criteria. The criteria are as follows.

Claims should be:

- Singular declarative sentences (i.e., not making more than one point);
- Complete sentences (not fragments);
- Precisely expressed with a potential truth value (not vague or ambiguous);
- Free of inference indicator words.

Once simple empirical claims are successfully used to clarify the notion of the claim, instructors can begin to use examples less reliant on a truth value, i.e., claims more subject to dispute and more likely to engender arguments. The second definition of a claim is apposite here: *an assertion that can be agreed with or disagreed with* (or partly agreed with). For example:

- *In a democracy, the poor have more power than the rich.*

This is not a simple empirical claim (there is no discoverable fact of the matter) yet it is a claim with a potential truth value—even if this is not easily ascertained. While not a claim with an empirical basis, the same criteria for claims still apply. Examples like this can lead to many useful departure points for instruction and debate.

Once appraised of the distinction between an empirical claim and a contestable claim, one can introduce the distinction between claims and reasons.

This is where inference indicator words become important. For example, it would be a mistake to include the following inference as a single claim in an argument map, because it contains two claims connected by the inference indicator ‘because’.

- *In a democracy the poor have more power than the rich, because there are more of them.*

i.e., not:

In a democracy the poor have more power than the rich, because there are more of them.

but instead:

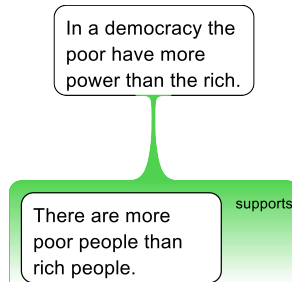

Figure 3. A claim compared to a contention with a reason

It should be made clear to students that there should be no reasoning going on *inside* a claim box. Students should watch out for typical inference indicator terms that occur in passages of text such as: *so, since, consequently, therefore, as a result/consequence, in view of the fact that, as shown by* (see Table 2, p. 134). These terms are represented as relationships between the claims and their location in the map rather than in the premise boxes themselves. *Because* in this example becomes an inference indicator (not part of the statement), and any claims in boxes are rendered as complete sentences (not fragments). This is important to stress because the argument mapping software doesn't check what the students put into the claim boxes. Without instructor input, students can create unintelligible maps because they put either multiple claims into each box or ungrammatical or fragmentary sentences that don't have a potential truth value.

It is also important to make clear to students that claims are *not* questions, commands, demands, exhortations, warnings, and so on. *Shut the door!* (a demand) is not a claim as it is not potentially true or false. Similarly, interrogative forms such as: *Is Sally going to McDonald's?* is not a claim. (One can-

not ask: Is the question: “*Is Sally going to McDonald’s?*” true or false?) By contrast, one can establish the truth of the assertion: *Sally is at McDonald’s*. Practice should be emphasised in establishing claims in key passages of text, identifying non-claims, and turning non-claims into claims.

It is generally helpful to make sure that claims are singular statements and do not include conjunctions (e.g., *and*, *but*, *moreover*) though there is nothing logically wrong with putting conjunctions into an argument map. Conjunctions are permitted in a single claim box if they *expand* or elaborate on a singular claim rather than add another. If they *add* another claim they must be treated differently. For example, take *Socrates is a man but he is not famous*. This is two separate claims: *Socrates is a man* AND *Socrates is not famous*—the first true; the second clearly false, and in an argument map we generally shouldn’t conflate them. These would be represented in separate claim boxes.

It is also important to stress that claims are always complete sentences. They should also be *clearly* potentially true or false: *Reshine moisturiser may make you look better* is not even a potentially clear claim (how would one decide if it is true or false?) whereas the more precise *Reshine moisturiser will make all your wrinkles disappear from your face within 24 hours* is a claim that is much easier to verify or falsify. Moreover, it seems to beg a reason (e.g., that Reshine moisturiser might have exfoliate properties) and this suggests at least that there might be some science behind this. In the latter case, but not the former, there is—potentially at least—a fact of the matter that can be empirically determined. All claims can be mapped, but those with reasons and evidentiary support will inevitably be seen as much stronger—as they should.

The distinction between (a) simple empirical claims; (b) contestable claims that unclearly expressed; and (c) clearly expressed contestable claims which potentially admit of reasons that could be potentially true or false, is fundamental to argument mapping and time needs to be given to explore the differences.

These points are important to establish early in argument mapping as one of the ways in which students can fail to map arguments properly is either by (a) constructing a map without claims at all; (b) using unclear claims or truth-dubious claims; or (c) putting more than one claim inside a reason, objection or contention box. Any of these can lead to poorly constructed maps. Argument mapping can help students understand why these problems are important, but the software doesn’t assess students’ work for these problems. Some programs however offer online tutorials² that cover some of these points. Importantly, students should be given time to play around with the argument

² <https://www.rationaleonline.com/docs/en/tutorials#tvty5fw>

mapping software being used, and to practice putting claims into boxes. Simple examples of prose, e.g., from Letters to the Editor, advertising slogans, or extracts from academic texts can be used for this purpose.

4. Sources of evidence and the provisional endpoints of arguments

Arguments and argument maps need to stop somewhere and where possible it is good practice to finish a line of reasoning with an evidence source that is uncontentious and can be accepted without further debate. Evidential sources come in many forms. For example, a person might accept the claim that he or she has disease x because they trust the expert opinion of their doctor. Evidence sources include assertions, data, common belief, case studies, legal judgements, expert opinion, personal experience, quotes, statistics, and so on. The argument mapping software *Rationale*TM allows users to represent sources of evidence as unique claim boxes that can be used to clearly mark the current endpoint of a line of reasoning (see Figures 4 and 5 below).

Of course, whether a source of evidence is uncontentious or not is provisional, and this provisional nature make the notion of an endpoint to an argument difficult to teach to students. Teachers need to make the point clear to students that *context matters* when deciding if a particular source of evidence can be used as an endpoint in an argument. It is probably fine to take the testimony of one's housemate that there is no milk in the fridge, but it is not acceptable to take for granted the assertion that Donald Trump is a part of a conspiracy of reptilian space aliens trying to take over the planet. It probably helps to reassure students that deciding on an acceptable endpoint to their argument is a very difficult thing to do and they can always revise their argument map at a later point in time if they tied off a line of debate too quickly.

Figure 4. Example of source of evidence used to end a line of reasoning. The argument mapping software *Rationale*TM has unique icons for different sources.

5. Arguments

Once the notion of a claim is clear, the concept of an argument needs to be introduced and applied using CAAM software. The notion of an argument, like the notion of claim, may also need some explanation. An argument *qua* an unpleasant interpersonal quarrel between individuals, is in such common use that it can be hard for students to see the alternative. The philosophical concept of an argument is typically defined as *a connected series of claims intending to establish some conclusion*, or variations on this, e.g., *a sequence of claims with an inference i.e., a logical move, to a conclusion/contention*. Students should be taught to appreciate that while claims are singular propositions only, arguments are—by definition—claims for which reason(s) are given. [See Chapters 8 and 9.]

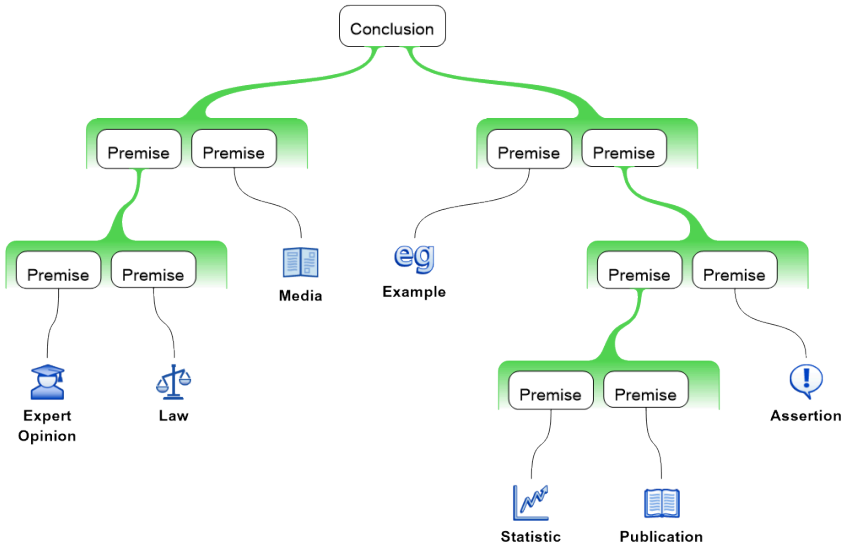

Figure 5. Ideally, a good argument map requires all premises to be either supported by further reasoning or provisional sources of evidence.

5.1 Simple, Complex and Multi-Layer Arguments

Early on, the distinction between *simple* and *complex* arguments should be made clear. A simple argument is one for which a single reason is given; a complex, or multi-reason argument—as the name suggests—is one with a set of reasons supporting a contention. Here is an example of each:

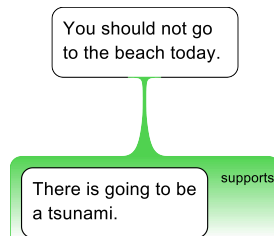

Figure 6. Simple argument with a single reason

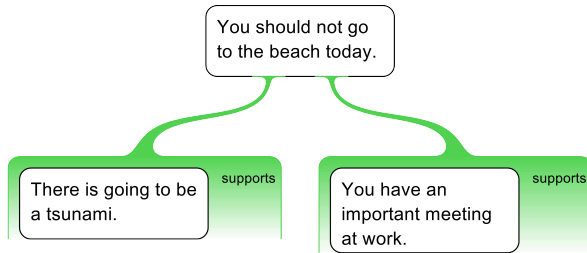

Figure 7. Complex argument with more than one reason

A key pitfall for students is in telling whether an argument has separate reasons working independently (as in this last example) or whether the reasons work together as dependent *co-premises*. We return to this later.

As students advance their understanding of argument mapping, *multi-layer* arguments can be introduced. These arguments have primary reasons supported by secondary level reasons.

An example is provided below. Here it should be noted that the contention of one argument can become a premise of another argument (see Figures 9 and 10 on the next page):

Figure 8. A multi-layer argument

It takes a great deal of practice for students to accurately reconstruct multi-layer arguments from a passage of raw text. Gratuitous assumptions are often made in authentic prose, premises are left out, and connections between premises and contentions are not clear. The job of the argument mapper is to make all connections between reasons and contentions, and between primary and secondary-level reasons very explicit. There is no substitute for a skilful pedagogy that builds student’s skills from achieving competence in analysing

and reconstructing simple and complex arguments, eventually to multi-layer arguments (naturally, mapping an argument does not imply one agrees with it):

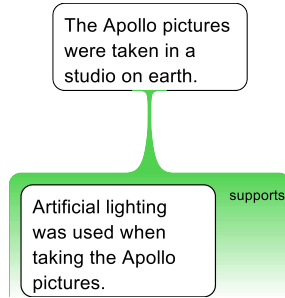

Figure 9. Example of a simple argument

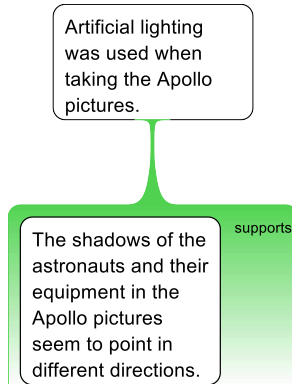

Figure 10. Using a premise in one argument as a contention in another

Expressed as a single multi-level argument, the two arguments in Figure 9 and Figure 10 become:

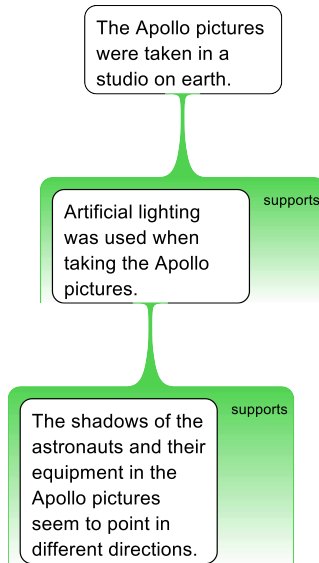

Figure 11. Example of a multilevel argument

6. Objections

The notion of an *objection* can be generally explained without difficulty as it mirrors the structure of reasons. Indeed, objections are simply reasons *against* something, and likewise, come in simple, complex and multi-layer variations.

When discussing objections, it should be made clear to students that objections can be supported by reasons—reasons here provide evidence that suggests an objection is a good one. For example, see Figure 12.

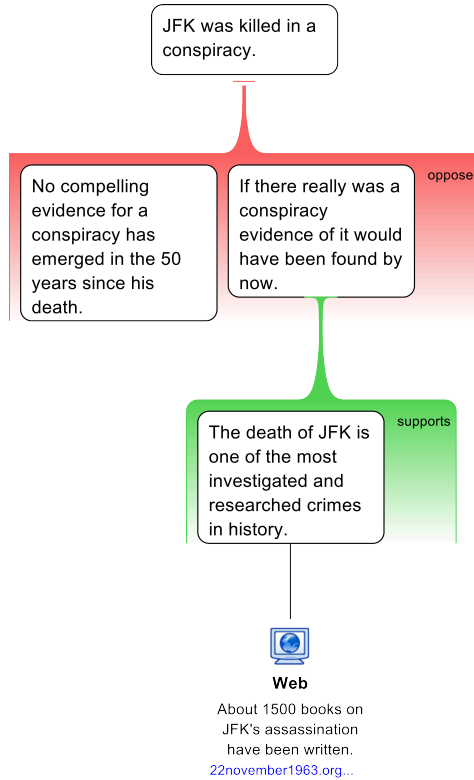

Figure 12. Supported objection

7. Ambiguity

Students should be made aware that very often passages of text are ambiguous. Argument mapping has to deal with such ambiguities. Is the following example a singular claim, or a claim for which a reason is given (an argument)? i.e., is it best rendered as a simple conditional claim?

If men have obtained advantages through past discrimination in their favour, then we may discount men's advantages when selecting people for jobs.

Figure 13. A conditional claim

Or should it be rendered as an argument (a contention with a premise offered in support of it)?:

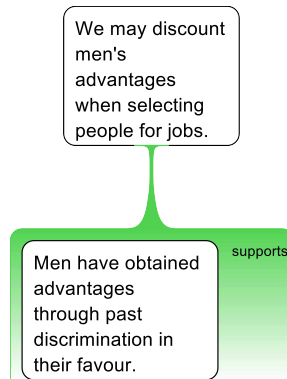

Figure 14. Example of a simple argument

Such examples are often context-dependent; a function of whether the author is trying to *convince* the reader of something, or whether they are merely asserting something. Class time should be devoted to looking at passages of text, establishing whether they are arguments or mere assertions and translating them into the argument mapping software.

As well as statements that could be arguments, there are also arguments that have implicit inferences that need elucidation. This phenomenon is very common. For example:

- *If you want a new car, now is the time and Hindmarsh is the place.*

This advertising slogan for a Building Society money-lender is probably best interpreted (charitably) as an argument, not merely a conditional statement. It is trying to convince us of something. Context, and knowledge of the role of money-lenders in society can help interpret it. A moment's reflection will tell us that the passage is trying to convince us that *we should borrow money from Hindmarsh*. Unfortunately for students, this contention is not present in the passage but must be gleaned from it. Indeed, the passage also intimates *we want a new car!* What seems like a simple conditional assertion appears to be a subtle argument with an intermediate conclusion and number of assumed premises. A possible interpretation of the argument is represented using the argument mapping software *Rationale*TM in Figure 15 on the next page.

No argument software can assist on its own with the interpretation of difficult passages of text like this, and an instructor's role is essential (Note that argument mapping convention requires that implicit or hidden claims, when explicated, are expressed in square brackets [...]).

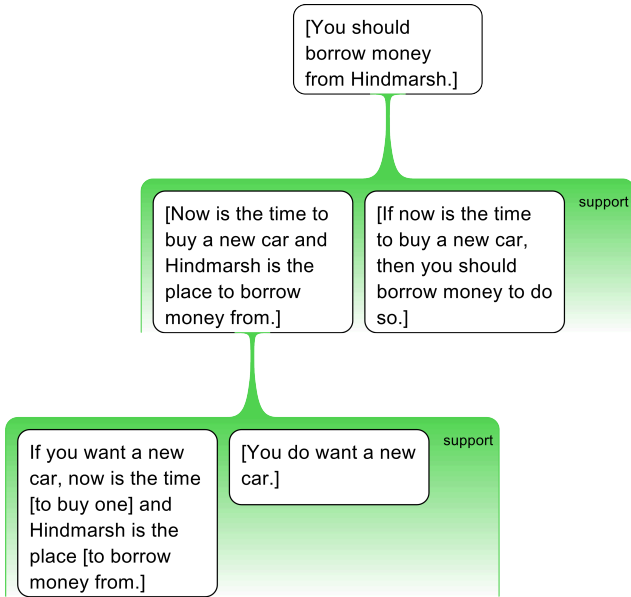

Figure 15. Complex enthymematic argument

Exposure to many different texts, and teaching sensitivity to argument context, can help. For example, the following advertising slogan:

- *The bigger the burger the better the burger, and the burgers are bigger at [Hungry] Jack's.*

conceals an implicit conclusion: *So/Therefore the burgers are better at [Hungry] Jack's.* Not including the contention renders the passage as a simple assertion rather than what it really is, namely, an argument with an implied contention—and a *non-sequitur* at that!

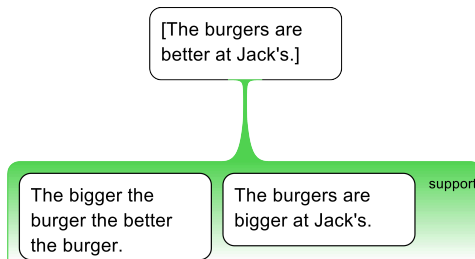

Figure 16. Simpler enthymematic argument

Enthymematic arguments (with suppressed claims) are difficult for students, and are commonplace in reasoning. In this example, these premises work together as co-premises to support the (implied) contention. We shall discuss how to deal with these below.

As well as dealing with enthymematic arguments, mapping is also helpful in clearly identifying and exposing instances of circular reasoning—where question-begging supporting reasons are provided, as Figure 17 indicates.

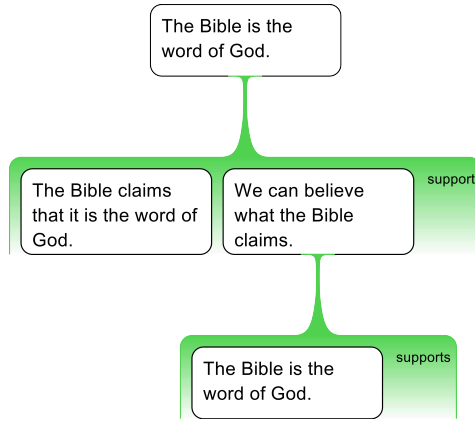

Figure 17. Example of a circular argument

8. Inference indicators

Early in class instruction it is important to introduce the idea of an *inference indicator*. There are two types: (a) reason indicators and (b) conclusion indicators. The difference between them is the role they play in an argument. It should be demonstrated how these words and phrases have different grammatical roles too. Reason indicators such as *because* point to the reason in a grammatical construction; conclusion indicators (like *so* and *therefore*) point to the contention. The role they play in sentence construction can be introduced and it can be shown how they can be transposed (see Tables 1 and 2 below).

Students should learn the different kinds of indicators to help determine what a reason is and what a conclusion is. They should be given practice in translating passages like these into simply box and arrow diagrams, or—if they are confident—into argument maps. A table showing how the indicators work can be helpful here (the examples provided below are not exhaustive).

Conclusion indicator pointing to a conclusion	...can be transposed to a reason indicator pointing to a reason
<i>The crops failed [implies] the Sun God is angry.</i>	<i>The Sun God is angry [since] the crops failed.</i>
<i>He had a low mark [consequently] he failed.</i>	<i>He failed, [as shown by] his low mark.</i>
<i>A strong work ethic [strongly suggests that] one will be successful.</i>	<i>Success in life is [strongly suggested by] one's work ethic.</i>
<i>You want to get a High Distinction [therefore] you should study hard.</i>	<i>You should study hard [because] you want to get a High Distinction</i>

Table 1. Transposition of conclusion and reason indicator words within sentences

At present, CAAM software has a limited range of inference indicators mostly using *because* or the neutral term *supports* exclusively (i.e., premise X *supports* contention Y; or X *because* Y). Students need to be able to translate the many inference indicators used in text into the blunt categories offered by CAAM software. This is one of its drawbacks. Future developments might address this. Given present limitations, it is important that students understand how to interpret ordinary language arguments replete in inference indicators of different kinds. Nothing substitutes for class work using passages of text that illuminate the many examples of indicator words in use.

<u>Conclusion indicators</u>	<u>Premise indicators</u>
Implies	Since
Therefore	As shown by
Hence	For
Thus	As
As shown by	In view of the fact that
So	Because
Consequently	Seeing that
It can be seen that	Is strongly suggested by
Strongly suggests that	

Table 2. Commonly-used conclusion and reason indicator words

9. Over-interpretation of inference indicators

When students are sufficiently informed about inference indicators, they can be prone to overuse their relevance and see arguments when they are not there. This is something the instructor needs to be wary of as well. Take, for

example, the sentence: *Sally said she was hungry before, so that is why you can see her eating a sandwich now.* This appears to have an inference connector, “so”, but the “so” functions grammatically to connect an explanation to an observation, not as an inference indicator. The passage is not *concluding* that you can see Sally eating a sandwich. Similarly, *Synonyms are good servants but bad masters, therefore select them with care.* This is not proffering a contention; it is best interpreted as a subtle piece of advice. Inference indicator words are thus not always indicating an inference (neither is the indicator word *thus* in that sentence). There is a difference between their use in inference-making and their use in grammatical construction. Again, lots of text-based practice is needed.

10. Tiers of Reasons/Objections: A procedural approach to argument mapping

We have mentioned that arguments can be represented in terms of tiers of reasons and objections in the form of multi-layered arguments. It is very easy for students to become overwhelmed by the difficulty of this task. How is this best taught and what are the things to watch out for?

As always, it is best to start with simple examples and then attempt more complex examples. The following example, the kind of thing to be found in a ‘Letter to the Editor’, provides an instructive case.

- *Dogs fetch balls and cats don't, so you can play with dogs. I mean, who'd disagree with that? It's obvious isn't it? You can't play with cats, of course. They are too stuck up. Dogs clearly make better pets.*

It is clearly an argument. How can one map it to clearly display the reasoning? To establish this, it is best to ask students to follow a series of steps. This is important as there is a strong tendency for students to jump into the task of mapping a passage without clearly thinking through the text, nor establishing the connections between the component parts of an argument.

Here is a suggested step-by-step approach that could be used with students to help them understand arguments. It is a good idea to ask students to follow these steps for any argument under consideration:

Step 1: Number the independent claims in any passage of text, ensuring that each claim is a singular statement or proposition. Assess each claim dispassionately. Ignore filler words like “Also”, “however”, or “clearly” which are not germane to the argument.

Upon completing this it is useful to:

Step 2: Establish the conclusion, which often needs to be ascertained without the help of inference indicators. Ask yourself: *What's the point?* Say *Convince me!* The contention being argued for will typically emerge naturally. Place this at the top of the map in a contention box (Note: it is possible to invert argument maps in some software, displaying contentions horizontally.)

This step is followed by:

Step 3: Eliminate redundancy. Ensure that each claim is a complete sentence and the text under consideration consists of stand-alone claims.

Eliminating the redundant expressions not germane to the argument, and the questions (non-claims), we get the following:

<1>Dogs fetch balls and cats don't, so <2>you can play with dogs. I mean, who'd disagree with that? It's obvious isn't it? <3>You can't play with cats, of course. They are too stuck up. <4>Dogs clearly make better pets.

The claims are as follows:

1. Dogs fetch balls and cats don't
2. You can play with dogs
3. You can't play with cats
4. Dogs make better pets

Using the *What's the point?* test mentioned above, the conclusion reveals itself to be the last claim <4>. This is placed at the top of the map, but how are the reasons supporting it to be arranged? The temptation might be that there are two independent reasons supporting the contention: *You can play with dogs* and *You can't play with cats*.

Figure 18. Complex argument

But this representation of the argument is missing something. What is to be done with claim <1> *Dogs fetch balls but cats don't*? At this point attention should be drawn to the inference indicator “so” that seems to draw a conclusion, i.e., it is not merely functioning grammatically in the sentence. But this “so” is clearly not an inference to claim <4>; it appears to be an inference to an intermediate conclusion that consists of claim <2> and thus should thus be represented in a multi-level argument like the maps below (Figures 19 and 20).

On reflection, it can be seen that that the two supporting reasons <2> and <3> are best rendered as a single claim—an intermediate conclusion (they are both making a point about “playing”)—and the claim about “fetching” can be seen as reasoned support for this. This captures the intended use of the connector word “so” linking <1> to <2>.

Figure 19. Multi-level argument

There is thus another rule to consider:

Step 4: Combine like claims into a single claim if they are making the same point.

The resulting argument map provides a clear example of serial reasoning that accurately represents the case being made:

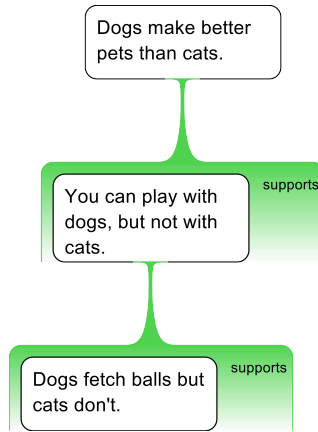

Figure 20. The argument exposed

In the case of more complex arguments additional principles need to be followed.

11. The principle of abstraction

A very useful guideline for argument mapping is the *principle of abstraction*. In many cases, the higher the claim in a multi-layered argument the greater the degree of abstraction; or to put it differently, the lower the claim the more specific it should be. In the above example, “playing” is more abstract than “fetching balls”, and both claims are less abstract than “better pet”. They provide serial support for each other. Students should be guided in how to apply this principle, as without this, maps can become a jumble of disorganized claims with no clear hierarchical structure. Once again, this requires practice and students should be given a number of exercises where they are required to rank claims in terms of their degree of abstraction. To our series of rules we can add the following:

Step 5: Generally try to ensure that higher-level claims are more abstract than lower-level claims

12. The principle of level consistency

Complex arguments have both a vertical and a horizontal axis. Arguments can be multi-layered along the vertical axis (as we have just seen), but premises

are present along a horizontal axis as well. Insofar as many premises can be brought to bear in an argument it is important to stress another principle, the *principle of level consistency*. Within each horizontal level, reasons or objections should be approximately of equal weighting in terms of their abstraction or generality. In the argument below this rule is not adhered to and is consequently hard to interpret.

The argument is improved by subordinating lower-level claims to a more general claim at the middle-level, and ensuring level consistency at the lower level, as shown on Figure 22.

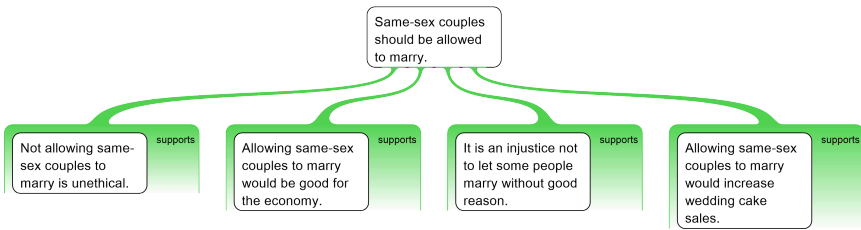

Figure 21. Lack of level consistency

Paying attention to the principle of level consistency we get:

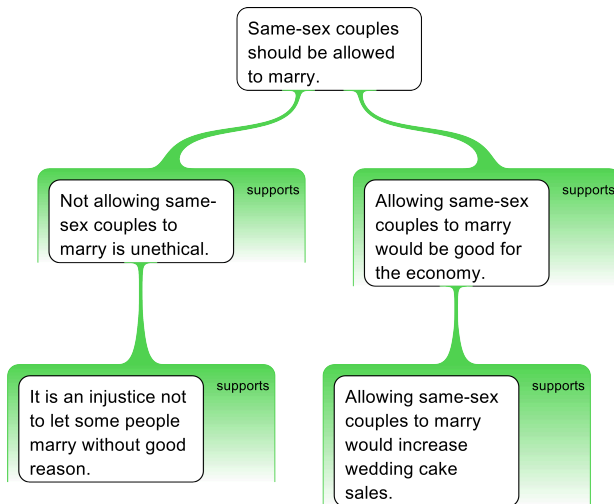

Figure 22. Applying level consistency

We can thus add another guideline:

Step 6: Aim for an equal weighting of premises in terms of level of generality across the horizontal axis of a multi-premise argument.

13. Missing Premises

Teaching students how to look out for missing premises is complex, but there are strategies that can help. It is difficult because reasoning is often replete in missing premises. Indeed, it is *very rare* that all premises are made explicit in reasoning. This is due to the implicit reliance of speakers or writers on the background beliefs assumed to be shared in any argumentative exchange. Here is a simple example.

- *Art must represent the world if it is to appeal to a broad audience for generations to come. So that's why Blue Poles will not appeal to a broad audience.*

In a normal human exchange, this would be a perfectly clear expression of a (rather dated) view about the painting *Blue Poles*. It is also an argument. We are given a reason for a conclusion, as indicated by the words “so that’s why”. However, when teaching argument mapping it is an example of an argument with a missing premise; a premise that needs to be exposed, and made clear. What, precisely, is being argued?

In this case, it is easy to see what is missing. It is the assumption that *Blue Poles does not represent the world*. Exposing this missing premise allows it to be evaluated, confirmed or rejected. In this example, the missing premise can be stated quite easily; in simple passages, this is often the case. But for more complex reasoning a series of steps need to be followed to ensure all missing premises are catered for. Fortunately, there is a very simple way to establish missing premises. This is done by applying two rules: *the Rabbit Rule* and *the Holding Hands Rule*. These rules are outlined in more detail in online tutorials available with the software *Rationale*TM.

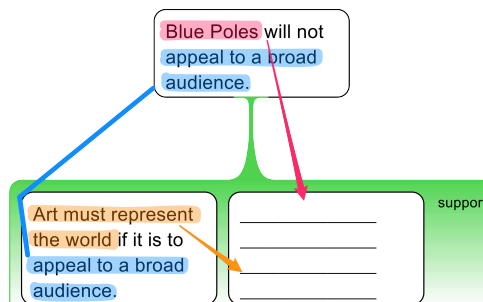

Figure 23. Determining a missing premise

14. Assumptions and how to find them using the Rabbit Rule and Holding Hands Rule

The Rabbit Rule is applied (vertically) to the inferential link between conclusion and the premises. This rule states that no conclusion should come out of thin air. (No rabbits out of hats!) The conclusion terms *appeal to a broad audience* appears in the available premise. We therefore know that *Blue Poles* must be supplied to the missing premise.

The Holding Hands Rule is applied horizontally between premises to any remaining terms after the Rabbit Rule has been applied (that is, if a term is not already supplied by means of the Rabbit Rule). The remaining terms must “hold hands” with another premise. No term can appear in one premise alone—there is always a companion term “holding hands”. In this example, we can see that *Art must represent the world* appears in the one premise, so too it must be present in the missing premise (see Figure 23). As the argument is *negating* something about *Blue Poles*, we similarly apply a corresponding negation to the terms of the missing premise. So *Blue Poles does not represent the world*.

We can add the following to our list of procedural rules to establish missing premises:

Step 7: Apply the Rabbit Rule and the Holding Hands Rule to make missing premises explicit in an argument map.

The argument can be expressed as follows:

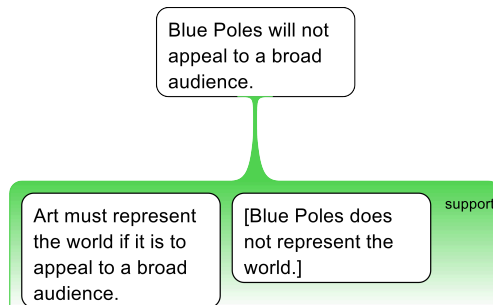

Figure 24. The argument exposed

It may not have escaped notice that the two claims that support the above contention are *jointly* necessary for the conclusion to follow. Strictly speaking they are not two *independent* reasons supporting the conclusion, but are co-

premises that jointly support the conclusion. This raises the important issue of co-premises or “linked” premises. This is another crucial methodological principle that students find difficult. Consider the following example:

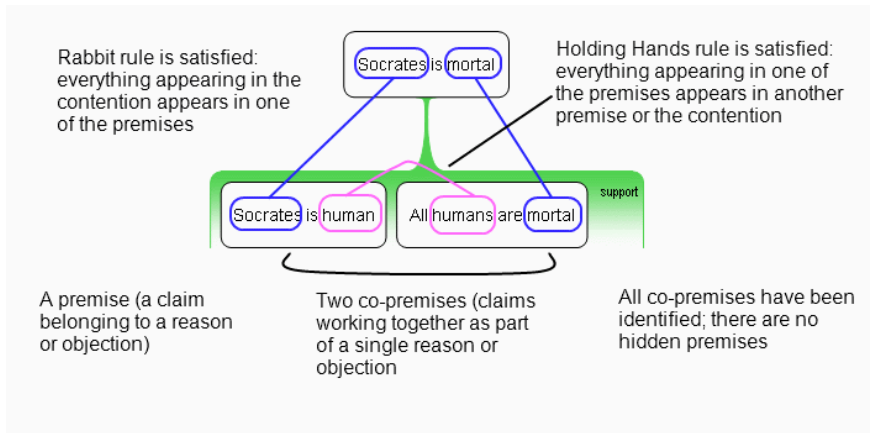

Figure 25. The Rabbit and Holding Hands rules

The above example (Figure 25) of a famous deductively valid argument in Philosophy demonstrates how both the Rabbit Rule and the Holding Hands Rule are satisfied. It also demonstrates an example of co-premises in action.

A co-premise is when two or more premises are jointly necessary for the truth of the conclusion. Co-premises are often enthymematic and sometimes a co-premise is trivial. For example, a person who reasons that they should rent a house because they should find a place to live as quickly as possible, tacitly assumes that renting a house is quickest way of finding a place to live.

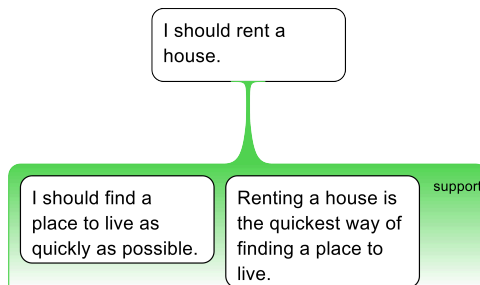

Figure 26. Example co-premise

Such assumed claims are often tacit in arguments in both writing and speech, and are often so trivial they do not need to be stated. However, they are an important feature of arguments. Indeed, every argument has at least two of

them. In CAAM this is often called “The Golden Rule”: *every argument has at least two co-premises*. In the example in Figure 27, we have extended the argument in Figure 20 by the addition of enthymematic co-premises.

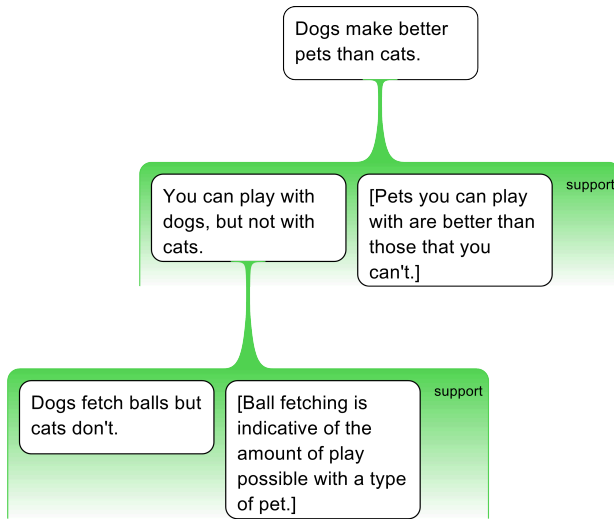

Figure 27. The Golden Rule applied

While ubiquitous in reasoning, co-premises are not always uncontroversial. Often, co-premises conceal hidden assumptions that are false or misleading. This is why it is good argument mapping practice to expose them. For example, it need not be accepted (without evidence—or even intuitively) that *Pets that you can play with make better pets than those you can't [play with]* (elderly people, the infirm or disabled, for example, like more docile pets). Being able to expose hidden assumption clearly for the purpose of critiquing them is a major advantage of argument mapping. Argument mapping software makes identification and representation of hidden claims easier by using color conventions and shading; however, this does not help students deciding how to determine how to locate a co-premise in a passage of text. Clear instruction and LAMP is needed. Probably the best way to approach co-premises in the classroom is to begin by discussing the differences between complex reasoning and linked reasoning.

15. Co-premises (Linked reasoning)

Students find the distinction between linked reasoning (dependent premises) and complex reasoning (independent premises) hard to grasp. It is best taught by showing students a number of multi-premise arguments and asking them to classify examples of complex and linked reasoning. In the “same sex”

example given earlier (Figure 22, p. 139), it is fairly easy to see that the supporting premises are independent and not necessary for each other.

Plausibly, neither premise could be true or both could; or one could be true, and the other false. If any one premise was true the conclusion could sensibly follow in either case. The conclusion could follow even if one of the claims was missing.

In other examples, co-premises are needed as the claims are not independent of each other and are examples of linked reasoning. For instance:

- *We should go to Rome for our holidays. Rome is beautiful. Also it will enable us to visit your relatives and this is something we really need to do.*

The passage, complete with numbered claims, would look like this:

- <1> *We should go to Rome for our holidays.* <2> *Rome is beautiful.* Also <3> *it will enable us to visit your relatives* and <4> *this is something we really need to do.*

How can one teach students which premises are linked and which are independent?

To our set of suggested procedural rules discussed earlier, we can add another step:

Step 8: Establish if any of the claims are linked or whether they stand-alone. Do this by assessing whether the conclusion can follow if any one of the claims was missing or false.

In convergent (or divergent) reasoning, none of the claims are dependent on any other claim; either one of the claims might support the conclusion alone. By contrast, in linked reasoning, the claims are not independent; they are necessary for each other for the conclusion to follow.

In the example above the claim *Rome is beautiful* is an independent reason (it does not depend on visiting relatives) and the contention *We should go to Rome for our holidays* can be supported by it. The contention can follow from *Rome being beautiful* regardless of the other claims provided. However, the claims about visiting the relatives appear to be linked. The claim: *This is something [Visiting your relatives] we really need to do* will not alone support the conclusion without including the claim *It [Visiting Rome] will enable us to visit your relatives*. Note however, this relationship is not symmetrical. Premise <3> can support the contention without premise <4>. However, <4> can't without <3>. If one premise can't support a conclusion without another premise, they can be said to be "linked".

With <2> as an independent premise, and <3> and <4> being linked premises, the map would appear as in Figure 28.

Figure 28. Example of linked reasons

A useful feature of argument mapping is the capacity to display linked premises in an intuitive visual way. Like other software, the software *Rationale*TM (used here) uses the color green for reasons and the color red for objections (the color orange is used exclusively for rebuttals, i.e., objections to objections). Co-premises are indicated by an umbrella shading that fades to white. This is a subtle visual indication that no argument is ever complete and more premises could potentially be added.

Objections too can be linked as co-premises as the following extension to the argument indicate. We have added a rebuttal against an objection (in orange) to demonstrate their use.

- *On the other hand <5> travelling to Rome is very expensive, primarily because <6> flights are so expensive. And <7> don't have a lot of money at the moment. But then again, <8> there is plenty of money in the children's bank account we could use.*

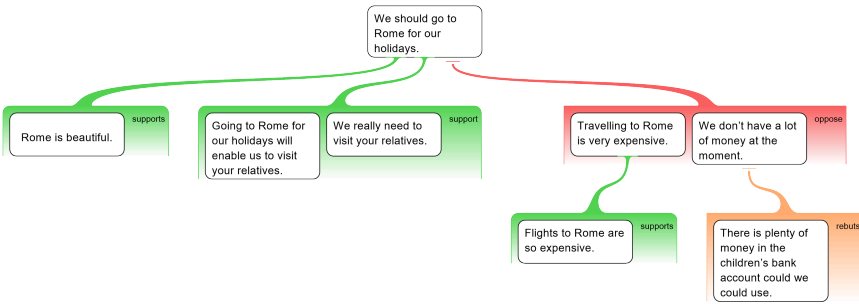

Figure 29. The argument exposed (with linked reasons and linked objections)

Note here that the claim that *Travelling to Rome is very expensive* could well object to the conclusion alone, but premise <7> could not (without premise <6>). The premises under consideration must *independently* support the conclusion to stand as independent reasons. If this is not the case, the premises are said to be linked.

16. A brief history of argument mapping

Argument mapping can be traced to the work of Richard Whately in his *Elements of Logic* (1834/1826) but his notation was not widely adopted. In the early twentieth century, John Henry Wigmore mapped legal reasoning using numbers to indicate premises (Wigmore, 1913; Wigmore, 1931). Monroe Beardsley developed this, and it became standard model of an argument map (Beardsley, 1950). On this approach, premises are numbered, a legend is provided to the claims identified by the numbers, and *serial*, *divergent* and *convergent* reasoning can be clearly represented. An example of each of these forms of reasoning using the standard model is provided below.

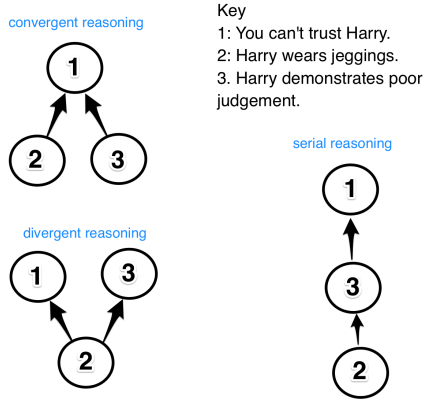

Figure 30. Serial, divergent and convergent maps using the Beardsley model

This model is still widely used and is advantageous in contexts where students are required to produce argument maps without access to software (e.g., in paper-based logic and reasoning exams under timed conditions).

In 1958, Stephen Toulmin devised another model of an argument map that included the notion of a “warrant” (which licenses the inference from the reasons, which he called “data”, to the claim), “backing” (which provides the authority for the warrant), modal qualifiers (such as “probably”), and “rebuttals” (which mention conditions restricting the inference) (Toulmin, 1958).

An example of a Toulmin map is provided in Figure 31.

Figure 31. Example of a Toulmin map

In 1973, Stephen N. Thomas refined Beardsley’s approach (Thomas, 1997/1973). Thomas included in his approach the important notion of “linked” arguments where two or more premises work together to support a conclusion (the distinction between dependent and independent premises having being

described earlier). This innovation made it feasible for arguments to include “hidden” premises. He is also said to have introduced the terms “argument diagram”, “basic” (or “simple”) reasons, i.e., those not supported by other reasons (as distinct from “complex” reasons). He also made the distinction between “intermediate” conclusions (a conclusion reached before a final conclusion) and a “final” conclusion (not used to support another conclusion). Thomas also suggested including objections as reasons *against* a proposition, and that these too should be included in argument maps.

In 1976, Michael Scriven proposed a procedure for mapping that could be recommended to students (Scriven, 1976). This involved a number of steps: (1) writing out the statements in an argument; (2) clarifying their meaning; (3) listing the statements, including any hidden claims; and (4) using numbers for premises along the lines of the Beardsley-Thomas model. In the case of hidden assumptions, Scriven’s notation used an alphabetical letter to distinguish hidden assumptions from explicit reasons. Scriven also emphasized the importance of a rebuttal in argument mapping, a notion identified earlier by Thomas.

In the 1990s a number of innovations occurred. Robert Horn helped popularize the notion of an argument map by producing idiosyncratic, large-format argument diagrams on key issues in philosophy such as “Can Computers Think?” (Horn, 1999; Horn, 2003). These maps did not adopt either the standard model or Toulmin-style notation for mapping arguments, but did use arrows and pictures to make the content clear, making it obvious for the first time that argument maps could be visually interesting as well as informative. These were distributed widely and used in class teaching. In addition, computer software programs began to be developed. This was important, as dedicated argument mapping software allowed premises to be composed, edited and placed within an argument map, as distinct from a legend alongside the map.

17. Argument mapping software

Once dedicated computer software was introduced, the standard model of numbered premises became outdated in all contexts outside its use in examinations. Several iterations of mapping software were developed in Australia and the U.S.A. with increasingly greater levels of sophistication. Tim van Gelder developed *Rationale*[™] and *bCisive*[™], the former designed as a basic argument mapping software, the latter designed for business decision-making applications (van Gelder, 2007, 2013). Both were later purchased by Dutch company Kritisch Denken BV.

A variety of argument mapping packages are now available, including *Araucaria*, *Compendium*, *Logos*, *Argunet*, *Theseus*, *Convince Me*, *LARGO*,

Athena, *Carneades* and *SEAS*. These range from single-user software such as *Rationale*TM, *Convince Me* and *Athena*; to small group software such as *Digalo*, *QuestMap*, *Compendium*, *Belvedere*, and *AcademicTalk*; to collaborative online debating tools for argumentation such as *Debategraph* and *Collaboratorium*. Enhancements to argument mapping software proceed apace. For example, there are moves to introduce a Bayesian network model to *Rationale*TM to cater for probabilistic reasoning.

*Rationale*TM or *bCisive* are perhaps the easiest programs to use for teaching argument mapping, but they require a subscription. Excellent free alternatives include the Argument Visualization mode in the online *MindMup*: <https://www.mindmup.com/tutorials/argument-visualization.html> and the cross-platform desktop package *iLogos*: <https://oli.cmu.edu/courses/argument-diagramming-open-free/> and new-comer: *Kialo*: <https://www.kialo.com/>

18. Argument mapping class room examples

There are a number of free argument resources available online.

- The designers of *Rationale*TM made tutorials to be used with their software. <https://www.rationaleonline.com/docs/en/tutorials#tvv5fw>
- Simon Cullen, who helped design the *MindMup* argument visualisation function, has posted some of the activities he uses for teaching philosophical arguments using argument maps. <http://www.philmaps.com>

19. Conclusion

In this chapter we have covered some of the basic concepts and considerations that teachers need to be aware of when using CAAM in the classroom. A set of procedural steps was suggested that is recommended for use with students. Understanding claims and arguments and how they are structured is only the start. Students should also be aware of how to interpret inference indicators, construct and analyse simple, complex and multi-layer arguments, and be able to integrate objections and rebuttals. They should be wary of misusing inference indicators, confusing reasons with evidence for reasons, and misinterpreting independent reasons for co-premises. There is much more we could have discussed. We have not touched on the use of inference objections (in contrast to premise objections). We have not mentioned argument webs or chains of reasoning, nor have we discussed in detail the appropriate ways to integrate evidence into an argument. However, it should be clear from this brief outline how CAAM can assist students in disentangling arguments in

everyday prose—replete, as it often is, with non-sequiturs, repetition, irrelevancies, unstated conclusions, and other infelicities.

About the authors:

Martin Davies is Principal Fellow in Higher Education in the Graduate School of Education at the University of Melbourne. He received the H. J. Allen Prize in Philosophy from the University of Adelaide in 2002. His work intersects philosophy and education, in particular, researching better ways of teaching critical thinking. He has a particular interest in computer-aided argument mapping. His most recent book is the edited collection (with Ronald Barnett): *The Palgrave Handbook of Critical Thinking in Higher Education* (2015). <http://www.martindavies.com.au>

Ashley Barnett has worked on several projects funded by the Intelligence Advanced Research Projects Activity (IARPA), including the design and evaluation of critical thinking and argument mapping courses for intelligence analysts. He enjoys making free online critical thinking and argument mapping courses.

Tim van Gelder is a Melbourne Enterprise Fellow in the School of Bio-Sciences, University of Melbourne, Australia. He is a Principal Investigator on the SWARM Project, a major effort to develop a cloud platform for collaborative analytical reasoning. He has contributed to the development of argument mapping tools and methods and research on the impact of their use on the development of critical thinking skills. His work has been funded by the Australian Research Council, including a Queen Elizabeth II Fellowship, and (currently) by IARPA, the US Intelligence Advanced Research Projects Activity. In addition to his academic activities he has considerable experience providing consulting and training services to large public and private sector organisations in areas such as reasoning, estimation, and decision making. He also keeps bees.
