Stillbirth should be given greater priority on the global health agenda

Stillbirths are largely excluded from international measures of mortality and morbidity. Zeshan Qureshi and colleagues argue that stillbirth should be higher on the global health agenda.

Zeshan U Qureshi academic clinical fellow in international child health, Joseph Millum bioethicist, Hannah Blencowe lecturer in infectious disease epidemiology, Maureen Kelley associate professor in bioethics, Edward Fottrell lecturer in epidemiology and global health metrics, Joy E Lawn professor in maternal, reproductive, and child health epidemiology, Anthony Costello professor in international child health, Tim Colbourn lecturer in global health epidemiology and evaluation

The global rate of stillbirths was estimated to be 18.9 per 1000 births in 2009, equating to a total of 2.64 million stillbirths, 1.2 million of which were during labour. The burden is heaviest for women in low and middle income countries and the poorest women in high income countries. Given its scale, stillbirth prevention should be high on the global health agenda. However, in the current draft of the United Nations sustainable development goals, which sets global targets for 2015-30, stillbirth is not mentioned, even though neonatal and under 5 mortality rates are included.

Explicit targets and accountability to track and reduce national stillbirth rates would help raise the political profile of stillbirths, engaging global leaders and increasing country government programmatic action. The Every Newborn action plan, which aims to provide all nations with a platform for ending preventable newborn deaths and stillbirths, proposed a target of reducing the stillbirth rate to ≤12 per 1000 births in every country by 2030. There is a strong case to be made at country and international levels that the introduction of stillbirth targets will encourage greater investment in perinatal care interventions. This has the potential to reduce neonatal and maternal deaths, as well as stillbirths, giving a triple return on programme investment and research.

In this article we argue for international adoption of the Every Newborn action plan stillbirth targets.

Definition

To facilitate international comparisons and improve measurement, the World Health Organization recommends a definition of stillbirth as late fetal loss with a birth weight of ≥1000 g or length ≥35 cm, or after 28 weeks. Many high income countries report stillbirths using additional definitions. For example, there is a cut-off of 24 weeks in the United Kingdom, 20 weeks (or 400 g) in Australia, and state variations in the United States. For this article, we use the international WHO definition because it is the only one with national and global estimates. If the definitions used in high income countries were applied, the international incidence of stillbirth would be even greater.

Burden and global health metrics

Rates of stillbirth were not mentioned in the UN millennium development goals, have not been counted in the Global Burden of Disease study, and are not routinely reported to WHO, even though the data are collected by some countries with vital registration and other systems. The first national estimates of stillbirth rates to be published were for the year 2000, and the first WHO national estimates were for the year 2009. For high income countries the data are substantial with narrow uncertainty, but for south Asia and sub-Saharan Africa, which have two thirds of the total global burden, the estimation uncertainty is wide.

In many low and middle income countries women may become pregnant and have a stillbirth without coming into contact with a healthcare professional. Thus most stillbirths are not officially recorded. National registration systems of all births, stillbirths, and other deaths are needed in every country. They are receiving more investment but will take time to reach scale in the poorest communities. This is a major challenge, particularly in remote communities.
settings. In the interim other large-scale data platforms, such as the District Health Information System, have started to count stillbirths. Household surveys such as the Demographic and Health Surveys also report stillbirths, but the quality of data has been questioned owing to recall bias, the difficulty of distinguishing between stillbirths and early neonatal deaths, and sensitivities around oral autopsies. 

The millennium development goals demonstrated that governments and donors are more likely to invest in programmes and tracking for outcomes that they have to account for publicly. Stillbirths and neonatal deaths should have similar value as early postnatal period. Stillbirth exacerbates this risk. For example, obstructed labour, common in low and middle income countries without access to good emergency obstetric care, is a cause of stillbirth and obstetric fistula. Stillbirth is also associated with short intervals between pregnancies. A data linkage study in England and Scotland found that women who had experienced a stillbirth or death of a child before the age of 1 were more likely to die in the first 15 years after the loss than the non-bereaved. This association remained significant at 35 year follow-up.

**Challenges and potential conflicts**

Advocates for women’s reproductive rights have voiced concerns about whether a greater emphasis on stillbirth prevention would conflict with women’s reproductive rights. Recognising stillbirths as equivalent to neonatal deaths raises questions about the moral status of all late term fetuses. Would this increase the profile of fetal rights and potentially impinge on the right to an abortion? The estimated 21.6 million unsafe abortions performed each year are a preventable cause of maternal morbidity and result in an estimated 47 000 maternal deaths a year. Most (98%) occur in low and middle income countries where abortion is usually illegal and is performed under unsafe conditions and where family planning services are also often lacking. However, almost all abortions occur well before 28 weeks, so do not fall under the WHO definition of stillbirth. In the UK, for example, 79% of abortions occur within the first 10 weeks of gestation, and less than 0.1% take place after 24 weeks. There is widespread ethical agreement that third trimester fetuses should have some protection from intentional termination. Even if late term abortion were considered a negative health outcome, the appropriate policy response would not necessarily be to limit access to late term abortions. It would more likely favour increasing the provision of family planning services and access to earlier abortions. There are other challenges to stillbirths being “counted.” Vital registration often relies on families registering the stillbirth themselves. Some communities associate stillbirth with maternal fault—for example, as an expression of her destiny, possession by evil spirits, or a punishment for previous sins. This may lead to stigma and marginalisation of the mother after reporting a stillbirth. Direct costs associated with registering a stillbirth include travel and lost productivity. In addition, distinguishing between stillbirth, miscarriage, and neonatal death may be difficult in settings where there have been no antenatal scans, the baby has never been weighed, and no healthcare professional has assessed the baby. Understanding such challenges is important for the design and implementation of routine systems to actively record stillbirths. Approaches used effectively in large scale population research may be good models for this. Recent advances in verbal autopsy tools offer ways to distinguish between early neonatal deaths and stillbirths. WHO led initiatives in this field have focused on simplifying data collection and analysis processes so that mortality surveillance, including stillbirths, is more easily implemented on a large scale routine basis in low and middle income countries. Using such methods to add stillbirths to countries’ existing mortality monitoring and reporting
responsibilities need not be at the expense of other mortality indicators.

Another possible concern about investing in preventing stillbirths and child deaths is that it might accelerate population growth. However, reducing child mortality is crucial to reducing fertility rates and consequent population growth. When parents believe their children are more likely to survive they tend to have fewer children. The same rationale is likely to apply to stillbirth prevention. In any case, the idea that we should address overpopulation by allowing preventable stillbirths and newborn deaths seems unethical.

Interventions

If stillbirth does gain a greater political profile, investment needs to be directed towards evidence based interventions that can successfully reduce stillbirth rates. Inclusion of stillbirths in economic evaluations of pregnancy and childbirth interventions increases their cost effectiveness. A systematic review of interventions against preventable perinatal deaths estimated that 531 000 stillbirths, 113 000 maternal deaths, and 1.325 million neonatal deaths could realistically be averted every year until 2020 for $4.5bn (£2.9bn; €4.0bn) a year or $0.90 per capita in the 75 highest burden countries. The focus of interventions depends on the setting. In low and middle income countries, where 98% of stillbirths occur, intrapartum stillbirths make up a higher percentage of the total stillbirth population (fig 1). Most of these stillbirths, particularly those that are intrapartum, are entirely preventable with known, effective interventions, including high quality basic antenatal care and care during labour (box). Advanced antenatal care, including fetal growth monitoring and accurate pregnancy dating with induction of post-term infants, is likely to be more relevant in middle and high income settings.

Conclusions

Collection of data about stillbirths and their prevention has low priority in global policy. Countries are directly accountable for their maternal and neonatal mortality rates but not stillbirth rates. Women’s reproductive health and rights are central to this debate. Raising the profile of stillbirths would enhance women’s reproductive rights, not reduce them. Counting stillbirths in health metrics and economic evaluations is long overdue. Without accelerated action, an additional 52 million stillbirths will occur between now and 2035. Having a specific stillbirth related target in the sustainable development goals could bring attention to this silent loss and halve this burden.

Contributors and sources: The authors bring a combination of expertise in epidemiology, economic evaluation, interventions, ethics, and advocacy. ZUQ wrote the first draft of the manuscript. TC, JM, JEL, HB, MK, EF, and AC contributed intellectual content and critical revisions to the manuscript. All authors approved the final manuscript. ZUQ is guarantor.

Competing interests: We have read and understood BMJ policy on declaration of interests and have no relevant interests to declare.

Interventions to reduce stillbirths

Prepregnancy and basic antenatal care
- Family planning and access to modern contraceptives
- Periconceptional folic acid supplementation or fortification
- Malaria in pregnancy prevention
- Syphilis detection and treatment

Advanced antenatal care*
- Detection and management of hypertensive disease of pregnancy, diabetes in pregnancy, and fetal growth restriction
- Identification and induction of mothers with 41 weeks of gestation or more

Childbirth care
- Skilled care at birth
- Basic and comprehensive emergency obstetric care

*Cost effective in middle and high income countries

Key messages
Stillbirths are largely excluded from international measures of mortality and morbidity and were not mentioned in the millennium development goals
Stillbirth rates have fallen much more slowly than maternal and child death rates, which do have specific millennium development goal targets
Stillbirths should be included in routine national and global health metrics and in economic evaluations of the cost effectiveness of options for health spending
Without clear national targets for prevention of stillbirths in the post-2015 development framework, there will continue to be little incentive to invest in interventions or in better stillbirth data
