The God-given Naturals: Induction and Recursion

Os Naturais que Deus nos deu: Indução e Recursão

Abstract
We discuss some basic issues underlying the natural numbers: induction and recursion. We examine recursive formulations and their use in establishing universal and particular properties.

Keywords: Naturals, induction, recursion, parameters, universal properties, particular properties.

Resumo
Nós discutimos alguns problemas básicos subjacentes aos números naturais. Examinamos as formulações recursivas e seu uso no estabelecimento de propriedades universais e particulares.

Palavras-chave: Naturais, indução, recursão, parâmetros, propriedades universais, propriedades particulares.

1. Initial Presentation

The present article is perhaps the last paper produced by Professor Paulo Veloso. It greatly expands on some ideas contained in (Porto, 2009) regarding Wittgenstein’s treatment of inductive proofs. In that paper, an alternative parametrized version of the usual recursive formulations of arithmetical operations is introduced. For example, in the case of addition, instead of the usual two clauses:

\[
\begin{align*}
    m + 0 &= m \\
    m + s(n) &= s(m + n)
\end{align*}
\]

we substitute the second clause of the definition by its parametrized version:

\[
\begin{align*}
    m + 0 &= m \\
    m + s^\alpha(n) &= s^\alpha(m + n)
\end{align*}
\]

which allow us to move \( \alpha \) successors in one single step. Once we have this new, parametrized recursive definition of addition, the usual inductive proof, say, of associativity of addition becomes simply:

\[
\begin{align*}
    a + (b + s^\alpha(0)) &= a + s^\alpha(b + 0) = s^\alpha(a + (b + 0)) = \\
    &= s^\alpha(a + b) = s^\alpha((a + b) + 0) = ((a + b) + s^\alpha(0))
\end{align*}
\]

The main goal of professor Veloso’s paper is to offer an extremely detailed comparison between usual inductive proofs with their parametrized versions, particularly with respect to universal/local validity, i.e., their validity with respect to non-standard models, and not only regarding the usual standard model. The paper retains the character of a work which was in progress. If it were not for his untimely death, professor Veloso would have certainly...
clarified better the logical instruments behind his proofs (first order logic, second order logic) as well as would have probably added parallel sections regarding universal/specific properties of Multiplication.

2. Introduction

We will examine some basic issues underlying the structure of the natural numbers: induction and recursion. In Section 3, we will use some simple examples to introduce recursive formulations and induction, stressing the distinction between universal and particular properties. In the remaining sections, we will examine other recursive formulations, as well as the role of induction in establishing properties of functions with recursive formulations, considering three approaches, which we called direct, reductive and algebraic ones. The first approach establishes a universal property directly by induction, whereas the other two approaches derive a property from other properties. We will be particularly interested in distinguishing universal properties, valid for all models, and merely local properties, valid only for the standard model.

3. Motivation: Recursion and Induction

We now use some simple examples to introduce the issues of recursion and induction. Consider the natural numbers. They can be visualized as follows:

\[ 0 \rightarrow 1 \rightarrow \cdots n \rightarrow n + 1 \rightarrow \cdots \]

In this structure, we have the natural number zero and the (unary) successor function: \( s(n) = n+1 \). In fact, the natural numbers are generated starting from zero by (iterated) applications of successor:

\[ 0 \overset{s}{\rightarrow} 1 \overset{s}{\rightarrow} \cdots n \overset{s}{\rightarrow} n + 1 \rightarrow \cdots \]

One can give recursive formulations for some operations on naturals. For instance, a recursive formulation for addition of naturals may be as follows

\[
\begin{align*}
(m + 0 &= m) & \text{case zero: } (0) \\
(m + s(n) &= s(m + n)) & \text{case non-zero: } (s)
\end{align*}
\]
This recursive formulation (+) reduces addition to iterated applications of the successor operation +. One often says that it defines the operation . It is used in establishing some properties of addition, such as commutativity (a+b = b+a) and associativity (a+(b+a) = (a+b)+c).

3.1. Double of Naturals

We will first examine the case of double the naturals. Consider the case of doubling of a natural: d(n)=2·n. A recursive formulation for function d reduces it to iterated double successors. It is as follows:

$$\left\{ \begin{array}{l}
  d(0) = 0 \\
  d(s(n)) = ss(d(n))
\end{array} \right. \quad \text{case zero: } (0) \quad \text{case non-zero: } (s)$$

With this formulation (d), one can evaluate the double of each natural. For instance, to evaluate $d(2)$, we can proceed as follows.

1. First, we express how 2 is generated: $2 = s(s(0))$.
2. Next, we use formulation (d) to evaluate $d(s(s(0)))$ as follows:

$$d(s(s(0)))^{(s)} = s\left(s\left(d(s(0))\right)\right)^{(s)} = s\left(s\left(s\left(s\left(d(0)\right)\right)\right)\right)^{(0)} = s\left(s\left(s\left(s(0)\right)\right)\right)$$

Finally, we note that $s(s(s(s(0))))$ denotes 4, by evaluating s, as follows:

$$s\left(s\left(s\left(s(0)\right)\right)\right) = s\left(s\left(s(1)\right)\right) = s(2) = s(3) = 4$$

The entire evaluation involves three steps as follows:

(r) first, we represent the argument $2 = s(s(0))$;
(d) next, we use formulation (d) to eliminate d;

1 A programmer would write (using predecessor $p$) $d(v) = \text{if } v = 0 \text{ then } 0 \text{ else } s\left(s\left(d\left(p\left(v\right)\right)\right)\right)$.

2 Note that the non-zero case (s) should be understood as $d(s(n)) = s(s(d(n)))$, for every natural $n \in \mathbb{N}$. So, formulation (d) abbreviates $d(0) = 0, d(s(0)) = s(s(d(0)))$. ...
(s) finally, we evaluate $s$, obtaining the natural $4 = s(s(s(0))))$.
These three steps can be summarized as follows

\[
\begin{array}{c}
d(2) \\
\hline
\text{represent} \downarrow \\
\text{d} \left(s(s(0))\right) \\
\text{eliminate} \text{ d} \\
\text{3 evaluate} s \\
\text{s} \left(s(s(0))\right)
\end{array}
\]

Two features of formulation (d) are apparent from this operational view:

- it eliminates the (new) symbol $d$: $d(s(s(0)))$ evaluates to $s(s(s(s(0))))$;
- the reduced name $s(s(s(s(0))))$ denotes the correct double of $2$.

One can also establish some properties of function $d$ in this manner. For instance:

(0) $0$ is its own double, as follows: $d(0) \overset{(0)}{=} 0$;
(+) a successor is not its own double, as follows: $d(s(n)) \overset{(s)}{=} s(s(d(n))) \neq 0$.

To clarify the matter, let us examine the language involved. Our language for the naturals has the symbols: constant $0$ (for zero) and unary function $s$ (for successor).

Within such a language, we have numerals as names for the naturals, as usual. For instance, $3 = sss(0)$ denotes the natural $3$, being a name for it. For each natural $n$, we introduce its numeral $\bar{n} := s^n(0)$ (where $s^n$ is a shorthand for $s \ldots s^n$).

We can see that the numeral $\bar{n}$ is a name for the natural $n$: it is a variable-free term denoting it. So, we see that every natural $n$ is (uniquely) denoted by its name $\bar{n} = s^n(0)$.

\[
\begin{array}{cccccc}
\to 0 & s & s(0) & \ldots & s^n(0) & s^{n+1}(0) & \ldots \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
0 & 1 & \ldots & n & n+1 & \ldots
\end{array}
\]

Thus, we have another natural formulation for double, as follows:

---

3 One can also introduce numerals by recursion (over $\mathbb{N}$): $\bar{0} = 0$ and $\bar{s(n)} := s(\bar{n})$. 

O que nos faz pensar, Rio de Janeiro, v.29, n.49, p.115-156, jul.-dez. 2021
This formulation (dbl) is just like the previous formulation (d).

\[
\begin{align*}
\text{dbl}[0] &= 0 \\
\text{dbl}[s(n)] &= s(s(\text{dbl}[n]))
\end{align*}
\]

\text{case } (0) \quad \text{case } (s)

We then have the following properties.

\(=\) f for \(n = 0\): \(\text{dbl}[n] \equiv n\) \quad \(0\) does equal its own double

\(\neq\) f for \(n \neq 0\): \(\neg \text{dbl}[n] \equiv n\) \quad a non-zero numeral is not its own double

So, we have \(\text{dbl}[\bar{n}] \equiv \bar{n} \rightarrow \bar{n} = 0\), for every natural \(n\). Have we actually established the universal property \(\forall v (\text{dbl}[v] \equiv v \rightarrow v = 0)\)? If all we know about is the above formulation (dbl), the answer is no!

To see this claim, consider a non-standard model of the naturals with zero and successor cf. (Herbert, 1972, pp. 178-183 §3), consisting of two chains: a \(\mathbb{N}\)-chain (the standard part) and a \(\mathbb{Z}\)-chain (the non-standard part) as follows:

\[
\begin{array}{c}
\cdots \\
\uparrow \\
\text{dbl} \quad +1 \\
\uparrow \\
0 \rightarrow 1 \rightarrow 2 \rightarrow \ldots \\
\text{n-chain} \\
\text{z-chain} \\
\uparrow \\
\pm 0 \\
\uparrow \\
-1 \\
\uparrow \\
\vdots
\end{array}
\]

In this structure, successor is indicated by the arrows. Now, let us define \(\text{dbl}\) on it as expected:

- on the standard part: \(\text{dbl}(n) = 2 \cdot n\);
- on the non-standard part: \(\text{dbl}(z) = 2 \cdot z\).

This expanded structure satisfies both clauses of the recursive formulation (dbl). The non-standard point \(\pm 0\) is a counterexample for the above uni-

---

4 Again, case (s) is be understood as \(\text{dbl}[s(n)] \equiv s(s(\text{dbl}[n]))\), for every natural .

5 Notice that only evaluation is required to establish each specific version.

6 In fact, it satisfies the universal sentence \(\forall v \text{dbl}[s(v)] \equiv s(s(\text{dbl}[v]))\).
versal formula: \( \pm 0 \neq 0 \) but \( \text{dbl}(\pm 0) = \pm 0 \), i.e., \( \pm 0 \) is a non-zero point that is its own double.

Now, let us take a closer look at what is happening with respect to induction. Let formula \( \varphi(v) \) be \( \text{dbl}[v] \doteq v \to v \doteq 0 \). Notice that we do have:

\[
(0) \text{ the basic instance } \varphi(0) \text{ trivially, as } 0 \doteq 0; \\
(s) \text{ each step instance } \varphi(n) \to \varphi(s(\bar{n})) \text{ since } \neg s(n^\perp) = \bar{n};
\]
as well as \( \varphi(n) \), for every natural \( n \). But we have failed to establish the universal formula \( \forall v \varphi(v) \). Why is this so?

Induction is a tool to establish universal properties. What is involved here might be called induction on names. It captures part of the intuition we have about the naturals; its shortcoming is that it covers only the standard part, and not all “possible” naturals.

In order to establish the universal property \( \forall v \varphi(v) \), one should use the induction schema

\[
[\varphi(0) \land \forall v (\varphi(v) \to \varphi(s(v)))] \to \forall v \varphi(v)
\]
or the induction rule

\[
\frac{\varphi(0) \quad \forall v (\varphi(v) \to \varphi(s(v)))}{\forall v \varphi(v)} \quad (IR)
\]

In both cases, we have to establish:

1. \((0)\) the basis \( \varphi(0) \) as before;
2. \((s)\) the induction step \( \forall v (\varphi(v) \to \varphi(s(v))) \) a universal formula.

In this case, we do have the basic instance \( \varphi(0) \), but can we establish the inductive step \( \forall v (\varphi(v) \to \varphi(s(v))) \)? To establish such a universal inductive step, we need a universal formulation for double, such as

\[
\begin{align*}
\{ \text{db}[0] & \doteq 0 \\
\forall v \text{db}[s(v)] & \doteq ss(\text{db}[v])
\end{align*}
\]

\text{case } (\bot) \text{ (db)}
With this formulation \( \text{db} \), the universal inductive step follows from \( \forall v \neg s(v) \neq 0 \). Therefore, we can infer the universal property \( \forall v \phi(v) \).

### 3.2. Addition of naturals

We now return to addition of naturals. Much as in the case of \( d \), we can use formulation \( + \) to evaluate specific cases of addition. For instance, consider \( 3+2 \) and \( 2+3 \).

1. We can evaluate \( 3+2 \) as follows

\[
3 + s(s(0)) \overset{(+) \quad s(3 + s(0)) \overset{(+) \quad s(s(3 + 0)) \overset{(+) \quad s(s(3)) = s(4) = 5}
\]

2. Similarly, we can evaluate \( 2 + 3 \) as follows

\[
2 + s(s(0)) \overset{(+) \quad s(2 + s(0)) \overset{(+) \quad s(s(2 + 0)) \overset{(+) \quad s(s(2)) = s(s(3)) = s(4) = 5}
\]

In this manner, we see the specific commutativity \( 3+2=2+3 \).

As in the case of double, we have another natural formulation for addition, namely:

\[
\begin{align*}
(\text{add}) & : m, 0 \rightarrow m \\
(\text{add}) & : m, s(n) \rightarrow s(\text{add}[m, n])
\end{align*}
\]

This formulation \( \text{add} \) is just like \( + \). So, for each given pair \( m \) and \( n \) of naturals, we can establish the specific commutativity \( \text{add}[\bar{m}, \bar{n}] = \text{add}[\bar{n}, \bar{m}] \) by evaluation and comparison.

We can proceed similarly for each given pair \( m \) and \( n \) of naturals.

1. Evaluate the left-hand side \( \text{add}[\bar{m}, \bar{n}] \).
2. Evaluate the right-hand side \( \text{add}[\bar{n}, \bar{m}] \).

---

7 We have \( \text{add}[\bar{m}, s'(0)] \overset{\text{add} \quad s(s(m)) \overset{(m)}{=} s((\cdots s (s(0)))}
\]

8 We have \( \text{add}[\bar{n}, s'(0)] \overset{\text{add} \quad s(s(n)) \overset{(m)}{=} s((\cdots s (s(0)))}
\]
3. Notice that both sides evaluate to the same natural.\(^9\)

Notice that we do not need induction to establish each given case \(\text{add}[\overline{m}, \overline{n}] = \text{add}[\overline{n}, \overline{m}]\).

Thus, we have the specific commutativity of addition:

\[(K+) \, \text{add}[\overline{m}, \overline{n}] = \text{add}[\overline{n}, \overline{m}], \text{ for each pair } m, n \text{ of naturals}\]

We cannot, however, establish the universal property \(\forall u \forall v \, \text{add}[u, v] = \text{add}[v, u]\)\(^10\).

To establish such a universal property, we need a universal formulation for addition, such as the following one:

\[
\begin{cases}
\forall u \, \text{add}[u, 0] = u \\
\forall u \forall v \, \text{add}[u, s(v)] = s(\text{add}[u, v])
\end{cases}
\]

To see the difference between this universal formulation \((\text{add})\) and formulation \((\text{add})\), notice that we can now have more general evaluations. For instance, we can now evaluate \(\text{add}[u, ss(0)]\) to \(ss(u)\) as follows:

\[
\text{add}[u, ss(0)] = ss(\text{add}[u, s(0)]) = ss(ss(u))
\]

With this formulation, one can establish the following universal properties of \(\text{add}\).

\[
\begin{align*}
(0+\_)& \text{ Left zero: } \forall v \, \text{add}[0,v] = v \quad \text{by induction on } v. \\
(s+\_)& \text{ Left successor: } \forall u \forall v \, \text{add}[s(u), v] = s(\text{add}[u,v]) \quad \text{by induction on } v. \\
(K+\_)& \forall u \forall v \, \text{add}[u,v] = \text{add}[v,u] \quad \text{using } (0+_\_) \text{ and } (s+_\_) \quad \text{by induction on } u.
\end{align*}
\]

Note that the above auxiliary properties \((0+\_)\) and \((s+\_)\) are special cases of commutative property \((K+\_)\). We also have specific instances of these auxiliary properties \((0+\_)\) and \((s+\_)\).

\[
\begin{align*}
(0+\_) \, \text{add}[0, \overline{n}] & = \overline{n}, \text{ for every natural } n \in \mathbb{N} \text{ (of } (0+\_)\text{)} \\
(s+\_) \, \text{add}[s(\overline{m}), \overline{n}] & = s(\text{add}[\overline{m}, \overline{n}]), \text{ for all naturals}
\end{align*}
\]

---

\(^9\) Both \(\overline{\overline{\ldots\overline{0}}}\) and \(\overline{\overline{\ldots\overline{0}}}\) have the same number of s's

\(^{10}\) We can argue much as in the case of \(\text{dbl}\): we expand the non-standard structure by \(\text{add}[a, n] = a + n\) and \(\text{add}[a, b] = b + 1\); then we satisfy both clauses of the formulation \((\text{add})\), but \(\text{add}[\pm 0, 0] = \pm 0\) whereas \(\text{add}[0, \pm 0] = \pm 0 + 1 = \pm 1\).
These specific versions, being special cases of the specific commutative property \((k+_{\downarrow})\), can also be established directly by evaluation and comparison. Some remarks about these ideas are in order.

1. We mentioned that we do not need induction to establish each specific version of commutativity of addition. So, induction appears to play no role in such cases. Actually, induction (on numerals) might come in handy to reuse cases previously established.\(^{11}\) For, all specific versions form an infinite set, so we have countably many induction-free proofs. Induction on \(\mathbb{N}\) may help condensing this countable set of proofs to finitely many proofs. This seems to be the usual case.\(^{12}\)

2. Similar methods, based on formulation \((ad)\), yield associativity of addition.
   - For the version \(\forall u \forall v \forall w \ ad(u,ad[v,w]) \doteq ad(ad[u,v],w)\), we use \((IR)\)\(^{13}\).
   - For the version \(\forall u \forall v \ ad(u,ad[v,k]) \doteq ad(ad[u,v],k)\), we can resort to evaluation and comparison.\(^{14}\)

3. The reason why these methods work so nicely for addition has to do with the rather simple nature of its recursive formulation (see Section 4). One can also establish properties of other operations, such as multiplication, by similar methods, but the details tend to be more involved.

We can now return to some distinctions universal versus particular properties and direct and reductive approaches. These examples help clarifying the distinction between universal and particular properties. The distinction between the direct, reductive and algebraic approaches will become clearer later on. Meanwhile, our examples can perhaps provide some clarification about the distinction between the direct and reductive approaches. Consider, for instance associativity of addition. On the one hand, the direct approach will establish its universal version directly by the induction rule \((IR)\). On the other hand, the reductive approach will establish its particular version by evaluating both sides, thereby reducing them to their normal forms, and comparing the results. The case of commutativity of addition is similar. The

\(^{11}\) Note that \(add[\vec{m},\vec{n}] \doteq add[\vec{n},\vec{m}]\) yields immediately \(add[\vec{m},s(\vec{n})] \doteq add[\vec{n},s(\vec{m})]\), by \((add.s)\).

\(^{12}\) We will examine such issues in Section 7 (see 7.2).

\(^{13}\) We can employ induction on \(w\) (see 6.1 in Section 6).

\(^{14}\) Both sides reduce to \(s^k(ad[u,v])\) (see 7.1 in Section 7).
so-called algebraic approach establishes a (universal) property by instan-
tiating general conditions.

The following table may be of help in clarifying these distinctions.

In the sequel, we shall take a closer look at some aspects of these questions. In the next section, we will examine universal recursive formulations.

4. Universal Recursive Formulations

We will now examine some examples of universal recursive formulations. We shall illustrate recursive formulations (in 4.1) and classify them (in 4.2).

4.1. Examples of recursive formulations

We will now illustrate recursive formulations for some functions.

We will consider universal formulations. To simplify the notation, howe-
ver, we will leave implicit the universal quantifiers. So, we write the formula-
tion , in Section 3, simply as

\[
\begin{align*}
\{ \text{ad}[u, 0] &= u \text{ case (1) (ad)} \\
\text{ad}[u, s(v)] &= s(\text{ad}[u, v]) \text{ case (2)} \}
\end{align*}
\]

As mentioned in Section 3, by relying on this formulation (ad), one can esta-
blish, by induction (IR), some properties of addition (see Section 6).

\[
\begin{align*}
(K+\forall) \forall u \forall v \text{ad}[u, v] = \text{ad}[v, u] & \text{ commutativity of +} \\
(++) \forall u \forall v \forall w \text{ad}(u, \text{ad}[v, w]) = \text{ad}(\text{ad}[u, v], w) & \text{ associativity of +}
\end{align*}
\]
Also, we write the formulation, in Section 3, simply as

\[
\begin{align*}
\{db[0]\} & \doteq 0 & \text{\textit{case (⊥)}} \\
\{db[s(v)]\} & \doteq ss(db[v]) & \text{\textit{case (⇒)}}
\end{align*}
\]

By relying on formulations (db) and (ad), one can establish, by induction (IR), the universal property \(\forall v \text{ db}[v] \doteq \text{ad}[v,v].\).\(^{15}\)

Other examples of recursive formulations are as follows.

\begin{enumerate}
\item (pd) Function predecessor \(pd\) has the following recursive formulation:

\[
\begin{align*}
\{pd[0]\} & \doteq 0 & \text{\textit{case (⊥)}} \\
\{pd[s(v)]\} & \doteq v & \text{\textit{case (⇒)}}
\end{align*}
\]

Formulation (pd) gives the property \(\forall v \text{ pd}[s(v)] = v.\)\(^{16}\)

\item (mn) For function minus, with \(a-b = a-b\) (for \(a \geq b\)) and \(a-b = 0\) (for \(a < b\)), we have the following recursive formulation (using function \(pd\))

\[
\begin{align*}
\{mn[u,0]\} & \doteq u & \text{\textit{case (⊥)}} \\
\{mn[u,s(v)]\} & \doteq pd(mn[u,v]) & \text{\textit{case (⇒)}}
\end{align*}
\]

Formulations (mn) and (pd) give the property \(\forall v \text{ mn}[0,v] = 0.\)

\item (mt) A recursive formulation for multiplication \(\cdot\) is as follows:

\[
\begin{align*}
\{mt[u,0]\} & \doteq 0 & \text{\textit{case (⊥)}} \\
\{mt[u,s(v)]\} & \doteq ad(u,mt[u,v]) & \text{\textit{case (⇒)}}
\end{align*}
\]

Formulation (mt) gives property \((K\cdot): \forall u\forall v \text{ mt}[u,v] \doteq \text{mt}[v,u].\)
\end{enumerate}

\(^{15}\) The formulations (db) and (add), in Section 3, would give the particular properties \(\text{dbl}[\bar{n}] = \text{ad}[\bar{n},\bar{n}],\) for every natural \(n \in \mathbb{N}.\)

\(^{16}\) Function successor has a recursive formulation: \(sc[0] = s(0); sc[s(v)] = s(sc[v]).\)
(sq) A recursive formulation for square is as follows:

\[
\begin{align*}
\text{(sq)} & : \\
\{sq[0] = 0\} & \quad \text{case (⊥)} \\
\{sq[s(v)] = s(\text{ad}(sq[v], db(v)))\} & \quad \text{case (⇒)}
\end{align*}
\]

Formulations (sq) and (mt) give the property \(\forall v \; sq[v] = mt[v, v]\).

(pw) A recursive formulation for exponentiation (with \(0^0 = 1\)) is as follows:

\[
\begin{align*}
\text{(pw)} & : \\
\{pw[u, 0] = s(0)\} & \quad \text{case (⊥)} \\
\{pw[u, s(v)] = mt(u, pw[u, v])\} & \quad \text{case (⇒)}
\end{align*}
\]

Formulation (pw) gives the property \(\forall u \; pw[u, s(0)] = u\).

4.2. Classes of recursive formulations

We will now classify our recursive formulations.

In each one of our recursive formulations in 4.1, the value of the function at the next input is computed from the present value: cf. case (⇒). There are, however, some distinctions.

1. In formulations (ad) and (mn), the value at the next input depends only on the present value. We may call them value recursive.

A value recursive formulation for a function \(f\) uses a unary step function \(h\) as follows

\[
\begin{align*}
\{ f[\underline{u}] = g(u) \} & \quad \text{case (⊥)} \\
\{ f[s(v)] = h(f[\underline{v}]) \} & \quad \text{case (⇒)}
\end{align*}
\]

The case of (db) also fits into this pattern: it has no parameter.

2. Formulations (mt) and (pw) are different: by clause (mt. ⇒), \(mt[u, s(v)]\) depends on both \(u\) and \(mt[u, v]\). Indeed, we evaluate \(mt[u, ss(0)]\) as follows:
In these formulations (mt) and (pw), the value at the next input depends on the parameter as well as on the present value. We may call them simple recursive.

A simple recursive formulation for a function \( f \) uses a step function \( h \) as follows

\[
\begin{align*}
  f \left[ \overline{u} \right] & \triangleq g(\overline{u}) & \text{case (1)} \\
  f \left[ s(v) \right] & \triangleq h \left( f \left[ \overline{u} \right] \right) & \text{case (\( \cdot \))}
\end{align*}
\]

Formulations (pd) and (sq) illustrate yet another difference: clause (pd.\( \triangleright \)) shows that \( pd[s(v)] \) depends on \( v \), rather than on the present value \( pd[v] \); its step function is the left projection \( \gamma \left( \frac{v}{w} \right) = v \). In these formulations (pd) and (sq), the value at the next input depends on the input.

In general, a primitive recursive formulation for a function \( f' \) uses a step function \( h' \) as follows

\[
\begin{align*}
  f' \left[ \overline{u} \right] & \triangleq g(\overline{u}) & \text{case (1)} \\
  f' \left[ s(v) \right] & \triangleq h' \left( f' \left[ \overline{u} \right] \right) & \text{case (\( \cdot \))}
\end{align*}
\]

Next, in Section 5, we will examine parameterization. In Section 6, we will examine how one can establish some universal properties of addition: associativity and commutativity.

5. Parameterization

We will now examine parameterization. Here, the motivation is the reduction to compositions of step functions. In Sections 3 and 4, we have examined some features of recursive formulations. This has clearly led to compositions of the step function, in the case of addition, but not quite so in the case of multiplication. Indeed, we have the following evaluations:
One way of approaching the goal of compositions of step functions is parameterization. We introduce the basic ideas with the simple case of addition (cf. formulation (ad) in 4.1). For each natural $m$, we define the parametrized addition $m \cdot ad[v] = ad[\bar{m}_v]$. So, we have the following connection between the two versions of addition:

$$\forall v \quad m \cdot ad[v] = ad[\bar{m}_v]$$

Thus, this unary function $m \cdot ad$ has the following (value) recursive formulation:

$$\begin{align*}
(m \cdot ad[0]) & = \bar{m} \\
(m \cdot ad[s(v)]) & = s(m \cdot ad[v])
\end{align*}$$

This formulation $(m \cdot ad)$ has basis value $\bar{m}$ (cf. $(\perp)$) and step function $s$ (cf. $(\triangleright)$).

We can compare these two versions of addition as follows:

<table>
<thead>
<tr>
<th>Function</th>
<th>arity</th>
<th>Basis</th>
<th>arity</th>
<th>Step</th>
<th>arity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Original</td>
<td>$ad[\bar{u}_v]$</td>
<td>2</td>
<td>$\iota(u) = u$</td>
<td>1</td>
<td>$s(w)$</td>
</tr>
<tr>
<td>Parametrized</td>
<td>$m \cdot ad[v]$</td>
<td>1</td>
<td>$\bar{m}$</td>
<td>0</td>
<td>$s(w)$</td>
</tr>
</tbody>
</table>

We can now examine the ideas underlying parameterization: parameterizing a function by fixing some of its arguments.

We parameterize a function $F: \mathbb{N}^n \times V \to W$ as follows: for each tuple $\bar{m} \in \mathbb{N}^n$ introduce its parameterized version $\bar{m} F: V \to W$ by:

$$\bar{m} F[v] = F(\bar{m}_v)$$

Parameterization constructs several new functions form a given one. We can compare these two versions of a function $F$ as follows:
5.1. Parameterization: value recursion

We will now examine parameterization for value recursive formulations (cf. 4.2). The case of monus (cf. 4.1) is entirely similar to addition. For each natural \( m \), we define parametrized monus \( \overline{m}mn \) by the following connection:

\[
\forall v \overline{m}mn[v] \equiv ad\left(\overline{m}\right)
\]

Thus, this unary function \( \overline{m}mn \) has a value recursive formulation much as \( \overline{m}ad \), with basis value \( \overline{m} \) and step function predecessor \( pd \).

It is not difficult to extend these ideas to value recursive functions (cf. 4.2). Consider a value recursive function \( f \) satisfying formulation (f). We introduce the unary parameterized version \( \overline{m}f \) by the following connection:

\[
\forall v \overline{m}f[v] \equiv f\left(\overline{m}\right)
\]

We now consider the unary parameterized version \( \overline{m}g = \overline{m}\overline{g} \) and noting that \( \overline{m}g \in \mathbb{N} \), we consider its numeral \( \overline{m}g = g(\overline{m}) \). Then, the parameterized version \( \overline{m}f \) has the following recursive formulation:

\[
\begin{align*}
\overline{m}f[0] & \equiv \overline{m}\overline{g} \\
\overline{m}f[s(v)] & \equiv h(\overline{m}f[v])
\end{align*}
\]

This formulation \( \overline{m}f \) has basis value \( \overline{m}\overline{g} \) and step function \( h \).

We can compare these two versions of a value recursive function as follows:
5.2. Parameterization: simple recursion

We now examine parameterization for simple recursive formulations (cf. 4.2). We will begin with parametrized multiplication \(_mmt[v] = mt[\bar{m}]\) for each natural \(m\), by the following connection:

\[
\forall v \; _mmt[v] = mt[\bar{m}]
\]

Thus, this unary function has the following recursive formulation:

\[
\begin{align*}
(\bar{m}mt[0]) & \equiv 0 \\
(\bar{m}mt[s(v)]) & \equiv _m ad(\bar{m}mt[v])
\end{align*}
\]

This formulation \(_mmt\) has basis value: \(0\) (cf. \(\bot\)) and step function: \(\bar{m}ad\) (cf. \(\triangleright\)). We can compare these two versions of multiplication as follows:

<table>
<thead>
<tr>
<th>Function</th>
<th>arity</th>
<th>Basis</th>
<th>arity</th>
<th>Step</th>
<th>arity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Original</td>
<td>([u/v])</td>
<td>(n+1)</td>
<td>(g(u))</td>
<td>(n)</td>
<td>(h(w))</td>
</tr>
<tr>
<td>(\bar{m}f[v])</td>
<td>(1)</td>
<td>(\bar{m}g)</td>
<td>(0)</td>
<td>(h(w))</td>
<td>(1)</td>
</tr>
</tbody>
</table>

The case of exponentiation (cf. 4.1) entirely similar to multiplication. For each natural \(m\), we define parametrized exponentiation \(_mpw, by the following connection:

\[
\forall v \; _mpw[v] = pw[\bar{m}]
\]

Thus, this unary function \(_mpw, mn\) has a value recursive formulation much as \(_mmt\), with basis value and step function parametrized multiplication \(_mmt\).
Much as before, we can extend these considerations to a simple recursive function (cf. formulation \((f')\) in 4.2). Consider a simple recursive function \(f'\) satisfying formulation \((f')\). We introduce the unary parameterized version \(\overline{m} f'\) by the following connection:

\[
\forall v \overline{m} f'[v] \doteq f' \left[ \overline{m} v \right]
\]

Introducing the unary parameterized version \(\overline{m} h[w] \doteq h \left[ \overline{m} w \right]\), we consider the numeral. Then, the parameterized version \(\overline{m} f\) has the following recursive formulation:

\[
\begin{cases}
{\overline{m} f}[0] \doteq \overline{m} g \\
{\overline{m} f}[s(v)] \doteq \overline{m} h(\overline{m} f[v])
\end{cases}
\]

This formulation \((\overline{m} f')\) has basis value \(\overline{m} g\) and step function \(\overline{m} h'\).

### 5.3 Parameterization: primitive recursion

We will now examine the general case of parameterization, namely functions with primitive recursive formulations (cf. 4.2); one can also parametrize them. Consider a primitive recursive function \(f'\) (cf. formulation \((f')\) in 4.2). As before, we introduce the unary parameterized version \(\overline{m} f'\) by the following connection:

\[
\forall v \overline{m} f'[v] \doteq f' \left[ \overline{m} v \right]
\]

Now, we consider the numeral \(\overline{m} g = g(\overline{m})\) and introduce the parameterized version \(\overline{m} h(\overline{v}) = h \left( \overline{m} v \right)\). Then, the parameterized version \(\overline{m} f\) has the following recursive formulation:

\[
\begin{cases}
{\overline{m} f}[0] \doteq \overline{m} g \\
{\overline{m} f}[s(v)] \doteq \overline{m} h(\overline{m} f[v])
\end{cases}
\]

Notice that the parametrized step function \(\overline{m} h(\overline{v}) = h \left( \overline{m} v \right)\) is no longer unary.

Notice that we take as parameters the inputs other than the recursive variable.
Now, consider functions without parameters, such as the unary functions \( \text{db}, \text{sq}, \) and \( \text{pd} \) (in 4.1). One could in principle apply the same idea to the recursive variable, but this does not seem to be of much help. Consider the case of unary predecessor. This function has no parameters. If we define \( \overline{m}\text{pd} = \text{pd}[\overline{m}] \), then will have distinct versions of predecessor, depending on the input \( \overline{m} \): \( \overline{m}\text{pd} = 0 \) and \( s(\overline{m})\text{pd} = n \). In the next section, we will examine iteration.

6. Addition: universal properties

We will now examine how one can establish some universal properties of addition. We will establish associativity (in 6.1) and commutativity (in 6.2), using the universal formulation \( \text{(ad)} \) (cf. 3.2 in Section 3).

6.1. Universal associativity of addition

Consider the following universal formulation of associativity of addition:

\[
(A\text{ad}_\gamma) \forall u \forall v \forall w \text{ad}\left(\frac{u}{ad\left(\frac{v}{w}\right)}\right) \equiv \text{ad}\left(\frac{ad\left[\frac{u}{w}\right]}{v}\right) \quad a + (b + c) = (a + b) + c
\]

We establish \( A\text{ad}_\gamma \) by (IR): induction on \( w \), using formulation in 3.2:

(0) Using \( \text{(ad}\perp) \) twice

\[
\text{ad}\left(\frac{u}{ad\left[\frac{v}{l0}\right]}\right) \overset{\text{(ad}\perp)}{=} \text{ad}\left[\frac{u}{v}\right] \overset{\text{(ad}\perp)}{=} \text{ad}\left(\frac{ad\left[\frac{u}{0}\right]}{v}\right)
\]

(s) Using \( \text{(ad}\triangleright) \) twice, \( \text{(HI)} \) and \( \text{(ad}\triangleright) \)

\[
\text{ad}\left(\frac{u}{ad\left[\frac{v}{s(w)}\right]}\right) \overset{\text{(ad}\triangleright)}{=} \text{ad}\left(\frac{ad\left[\frac{u}{w}\right]}{s(w)}\right)
\]

\[
\text{ad}\left(\frac{s\left(\frac{u}{ad\left[\frac{v}{w}\right]}\right)}{s(w)}\right) \overset{\text{(HI)}}{=} \text{ad}\left(\frac{ad\left[\frac{u}{w}\right]}{s(w)}\right)
\]
6.2. Universal commutativity of addition

We will now examine how one can establish the universal commutativity of addition. Consider the following universal formulation of commutativity of addition:

\[(Kad_{\forall}) \forall u \forall v \; ad \begin{bmatrix} u \end{bmatrix} = ad \begin{bmatrix} v \end{bmatrix} \quad a + b = b + a\]

We will establish \((Kad_{\forall})\) by using its two special cases (cf. Section 3):

\[(0ad_{\forall}) \forall v \; ad \begin{bmatrix} 0 \end{bmatrix} = v \quad \text{left zero: } 0 + b = b\]

\[(sad_{\forall}) \forall u \forall v \; ad \begin{bmatrix} s(u) \end{bmatrix} = s \left( ad \begin{bmatrix} v \end{bmatrix} \right) \quad \text{left succ: } a + s(b) = s(a + b)\]

We first note that the, in the presence of formulation \((ad)\), two properties \((0ad_{\forall})\): left zero and \((sad_{\forall})\): left successor are special instances of \((Kad_{\forall})\) commutativity.

\[\left( (Kad_{\forall}) \vdash^{ad} (0ad_{\forall}) \right) :(\forall u \forall v \; ad \begin{bmatrix} u \end{bmatrix} = ad \begin{bmatrix} v \end{bmatrix} ) \vdash \forall v \; ad \begin{bmatrix} 0 \end{bmatrix} = v \quad \text{with } u = 0^{17}\]

\[\left( (Kad_{\forall}) \vdash^{ad} (sad_{\forall}) \right) :(\forall u \forall v \; ad \begin{bmatrix} u \end{bmatrix} = ad \begin{bmatrix} v \end{bmatrix} ) \vdash \forall v \forall v \forall ad \begin{bmatrix} s(u) \end{bmatrix} = s \left( ad \begin{bmatrix} v \end{bmatrix} \right) \quad \text{with } u = s(u)^{18}\]

We now establish these three properties by (IR), using formulation \((ad)\) in 3.2.

\[(0ad_{\forall}) \forall v \; ad \begin{bmatrix} 0 \end{bmatrix} = v \quad \text{(left zero)} \quad \text{by (IR): on } v, \text{with (ad)}\]

(0) Direct by \((ad.\perp)\)

\[ad \begin{bmatrix} 0 \end{bmatrix}^{(ad.\perp)} = 0\]

---

17 Indeed \(ad \begin{bmatrix} 0 \end{bmatrix}^{(Kad_{\forall})} = ad[0,0]^{(ad.\perp)} = v\).

18 Indeed \(ad \begin{bmatrix} s(u) \end{bmatrix}^{(Kad_{\forall})} = ad[s(0)]^{(ad.\perp)} = s \left( ad \begin{bmatrix} 0 \end{bmatrix} \right)\)
(s) Using \((\text{ad} \triangleleft)\) and \((\text{HI})\)

\[
\text{s}\left(\text{ad}\left[0\right]_{\text{v}}\right) \stackrel{(\text{HI})}{=} \text{s}(v)
\]

\((\text{sad}_v) \forall u \forall v \ \text{ad}\left[u\right]_{\text{v}} \triangleq \text{s}(\text{ad}\left[u\right]_{\text{v}}) \quad \text{(left successor)} \quad \text{by (IR): on } v, \text{ with(\text{ad})}\)

(0) Using \((\text{ad} \perp)\) twice

\[
\text{ad}\left[0\right]_{\text{v}} \stackrel{(\text{ad} \perp)}{=} \text{s}(u) \stackrel{(\text{ad} \perp)}{=} \text{s}(\text{ad}\left[0\right]_{\text{v}})
\]

(s) Using \((\text{ad} \triangleright)\), \((\text{HI})\) and \((\text{ad} \triangleright)\)

\[
\text{s}\left(\text{ad}\left[u\right]_{\text{v}}\right) \stackrel{(\text{HI})}{=} \text{s}(\text{ad}\left[u\right]_{\text{v}}) \quad \text{by (IR): on } u, \text{ with(\text{ad}), (0\text{ad}_v)}, (\text{sad}_v)
\]

(0) Using \((0\text{ad}_v)\) and \((\text{ad} \perp)\)

\[
\text{ad}\left[0\right]_{\text{v}} \stackrel{(0\text{ad}_v)}{=} v \stackrel{(\text{ad} \perp)}{=} \text{ad}\left[0\right]_{\text{v}}
\]

(s) Using \((\text{ad} \triangleright)\), \((\text{HI})\) and

\[
\text{s}\left(\text{ad}\left[u\right]_{\text{v}}\right) \stackrel{(\text{HI})}{=} \text{s}(\text{ad}\left[u\right]_{\text{v}}) \quad \text{by (IR): on } u, \text{ with(\text{ad})}
\]

\[
\text{ad}\left[u\right]_{\text{v}} \stackrel{(\text{sad}_v)}{=} \text{ad}\left[u\right]_{\text{s}(v)}
\]
Table 1 compares the proof structures for these three universal commutativity-related properties of addition.

7. Addition: specific properties

We will now examine how one can establish some specific properties of addition. We will establish associativity (in 7.1) and commutativity (in 7.2), using the universal formulation (cf. 3.2 in Section 3). For such specific properties, one can avoid the induction rule, by resorting to auxiliary properties (established by induction on). For addition, the idea is (partially) reducing it to composition of successors.

We introduce the composites of a unary function, as expected. Given a unary function $t: W \rightarrow W$, we define its $k$-composite $t^k : W \rightarrow W$, for each $k \in \mathbb{N}$, by the following recursion (over $\mathbb{N}$)

$$t^0 [w] = w, \quad t^{(k)} [w] = t(t^{k-1} [w])$$

Thus, $t^k [w] = t \underset{k}{\underbrace{\ldots t [w]}}$.\(^{19}\)

The following commutativities of composites are clear.\(^{20}\)

---

\(^{19}\) One could also introduce the iteration $t^* [v,w]$ (with a new variable $v$ giving the number of iterations) by the recursion $t^* [0,w] = w$ and $t^* [s(v),w] = t(t^* [v,w])$

\(^{20}\) The instance $(s^* s^m)$ of property $(t^* t^m)$ will be used for establishing commutativity of addition.
\[(tt^n) \text{ Function and composite: } \forall w \ t(t^n[w]) = t^n(t[w]) \quad t^\frac{n}{t} \ldots t^\frac{n}{n} (a) = t^\frac{n}{t} \ldots t^\frac{n}{n} (a)\]

\[(t^n m) \text{ Composite: } \forall w \ t^n(t^m[w]) = t^m(t^n[w]) \quad t^\frac{n}{t} \ldots t^\frac{n}{m} \ldots t^\frac{n}{n} (a) = t^\frac{n}{t} \ldots t^\frac{n}{m} \ldots t^\frac{n}{n} (a)\]

Equation \((tt^n)\) follows by induction on \(n \in \mathbb{N}\).\(^{21}\) Now, equation \((t^n t^m)\) follows also by induction on \(n \in \mathbb{N}\).\(^{22}\)

Also, consider the generalizations of \((\text{ad.} \triangleright)\) and \((\text{ad.} \triangleright)\) to composite successors as follows.

\[(\text{ad } s^k) \text{ Addition of composite successors } a + s^k(b) = s^k(a + b)\]

\[\forall u \forall v [s^k(u/v)] = s^k(\text{ad } [u/v]), \text{ for every } k \in \mathbb{N}\]

\[(\text{ad } k) \text{ Addition of numeral } a + s^k(0) = s^k(a)\]

\[\forall u \text{ ad } [u/k] = s^k(u), \text{ for every } k \in \mathbb{N}\]

The proof of \((\text{ad } s^k)\) is by induction on \(k \in \mathbb{N}\). Now, \((\text{ad } s^k)\) and \((\text{ad.} \bot)\) entail \((\text{ad } k)\).

\[\text{7.1. Specific associativity of addition}\]

We will now examine how one can establish a specific version of associativity of addition. Consider the following specific version of associativity of addition \((a + (b+k) = (a+b)+k)\):

\[(\text{Aad.}) \forall u \forall v \text{ ad } \left(\text{ad } [u/v]\right) = \text{ad } \left(\text{ad } [u/v]\right), \text{ for every natural } k \in \mathbb{N}\]

With equations \((\text{ad } k)\) and \((\text{ad } s^k)\), we can establish directly this associative property \((\text{Aad.})\) as follows:

\[21 \quad (0): t(t^n[w]) = t[w] = t^n(t[w]), \quad (s): t\{t^{(s^n)}[w]\} = t(t^n(t[w])) \quad (\text{NN})\]

\[22 \quad (0): t^0(t^m[w]) = t^m[w] = t^m(t^0[w]), \quad (s): t\{t^{(s^n)}[w]\} = t(t^n(t^m[w])) \quad (\text{NN})\]

---

\[O \text{ que nos faz pensar, Rio de Janeiro, v.29, n.49, p.115-156, jul.-dez.2021}\]
7.2. Specific commutativity of addition

We will now examine how one can establish particular versions of commutativity of addition. Consider the following quantifier-free version of commutativity of addition:

\[(Kad_1) \quad ad\left[\overline{m},\overline{n}\right] = ad\left[\overline{n},\overline{m}\right], \text{for every natural } m, n \in \mathbb{N}\]

With \((ad\,\overline{n})\) instance \((s^n s^m)\) (of \((t^n t^m)\) \((s^n s^m))\) and \((ad\,\overline{m})\), one can show directly this commutative property \((K+↓)\) as follows:

\[ad\left[\overline{m},\overline{n}\right] = s^n (s^m (0)) = s^m (s^n (0)) = s^m (\overline{n}) = ad\left[\overline{n},\overline{m}\right]\]

8. General Conditions: value recursion

We will now examine some general conditions for two properties of a value recursive binary operation (cf. 4.2 in Section 4). Consider a binary function \(q\) with the following universal value recursive formulation:

This formulation has unary basis function \(e(u)\) and unary step function \(r(w)\).

We wish to establish conditions for some properties of such a binary operation \(q\). We will examine conditions for commutativity (in 8.1) and for associativity (in 8.2).
8.1 Conditions for commutativity: value recursion

We will now characterize the commutative value recursive binary operations. Consider the following universal formulation of commutativity of $q$:

$$(K_{q_{v}}) \forall x \forall y \ q \left[ \frac{x}{y} \right] \equiv q \left[ \frac{y}{x} \right] \quad aqb = bqa$$

Analogy with addition suggests the following two universal properties.

$$(0_{q_{v}}) \forall v \ q \left[ \frac{0}{v} \right] \equiv e(v) \quad \text{Value at left zero: } 0 \ q b = e(b)$$

$$(s_{q_{v}}) \forall u \forall v \ q \left[ \frac{s(u)}{v} \right] \equiv r \left( q \left[ \frac{u}{v} \right] \right) \quad \text{Value at left successor: } s(a) \ q b = r(a \ q b)$$

Now, consider $3 \ q 2$ and $2 \ q 3$. Let us evaluate them and compare the results. The above formulation (q) evaluates them as follows.

$$(\overline{3q2}) \text{ It evaluates } q \left[ \frac{3}{2} \right] \text{ to } (r^2 e s^3)(0) = (r \ r \ e \ s \ s \ s)(0) \text{ as follows:}$$

$$q \left[ \frac{3}{ss(0)} \right] \overset{(e)}{=} r \left( q \left[ \frac{3}{ss(0)} \right] \right) \overset{(e)}{=} r \left( r \left( q \left[ \frac{3}{s(0)} \right] \right) \right) \overset{(i)}{=} r \left( r \left( e(3) \right) \right) = r \left( r \left( e(sss(0)) \right) \right)$$

$$(\overline{2q3}) \text{ It evaluates } q \left[ \frac{2}{ss(0)} \right] \text{ to } (r^3 e s^2)(0) := (r \ r \ r \ e \ s \ s)(0) \text{ as follows:}$$

$$q \left[ \frac{2}{ss(0)} \right] \overset{(e)}{=} r \left( q \left[ \frac{2}{ss(0)} \right] \right) \overset{(e)}{=} r \left( r \left( q \left[ \frac{2}{s(0)} \right] \right) \right) \overset{(e)}{=} r \left( r \left( r \left( q \left[ \frac{2}{0} \right] \right) \right) \right) \overset{(i)}{=} r \left( r \left( r \left( e(2) \right) \right) \right)$$

If we had $e \ s = r \ e$, then both results $(r^2 e s^3)(0)$ and $(r^3 e s^2)(0)$ would be equal.\(^{23}\) This example suggests yet another universal condition, as follows.

$$(es_{v}) \forall w \ e[s(w)] \equiv r(e[w]) \quad \text{Basis at successor is step at basis: } [e \ s](b) = [r \ e](b)$$

$$\begin{array}{c}
W \xrightarrow{s} W \\
\downarrow e \quad \downarrow e \\
W \xrightarrow{r} W
\end{array}$$

\(^{23}\) Indeed, both $r^2 e s^1$ and $r^1 e s^2$ would be equal to $r^2 e: r^2 e s^3 = r^2 e s s = r^2 r e s = r^3 r r r e$, and $r^3 e s^2 = r^3 e s s = r^3 r e s = r^3 r r e$.  

---

O que nos faz pensar, Rio de Janeiro, v.29, n.49, p.115-156, jul.-dez.2021
We can now see that we have two alternative characterizations for commutativity. For a binary operation $q$ satisfying the value recursive formulation $(q)$, the following conditions are equivalent.

$$(Kq_y) \ \forall x \forall y \ q \left[\frac{x}{y}\right] = q \left[\frac{y}{x}\right] \quad \text{commutativity of } q$$

$$(Vq_y) \ \text{Values } (0q_y) \ \forall v \ q \left[\frac{0}{v}\right] \doteq e(v) \ & \ (sq_y) : \ \forall u \forall v \ q \left[\frac{s(u)}{v}\right] \doteq r \left( q \left[\frac{u}{v}\right] \right)$$

$$(es_y) \ \forall w \ e[s(w)] \doteq r[e(w)] \quad \text{basis at successor is step at basis}$$

Proof: We will show $(Kq_y) \Rightarrow (es_y) \Rightarrow (Vq_y) \Rightarrow (Kq_y)$.

$(Kq_y) \Rightarrow (es_y)$ Commutativity of $q$ yields, by $(q)$, $(es_y)$ as follows:

$$e[s(w)] \overset{(q, \perp)}{=} q \left[\frac{s(w)}{0}\right] \overset{(Kq)}{=} q \left[\frac{0}{s(w)}\right] \overset{r}{=} q \left[\frac{0}{w}\right] \overset{(Kq)}{=} r \left( q \left[\frac{w}{0}\right] \right) \overset{(q, \perp)}{=} r[e(w)]$$

$(es_y) \Rightarrow (Vq_y)$ We show $(es_y) \Rightarrow (0q_y)$ and $(es_y) \Rightarrow (sq_y)$, both by induction on $v$, using $(q)$.

$(es_y) \Rightarrow (0q_y)$ By induction on $v$, using $(q)$.

$$(0): q \left[\frac{0}{0}\right] \overset{(q, \perp)}{=} e(0); \quad (s): q \left[\frac{0}{s(v)}\right] \overset{(q, \perp)}{=} r \left( q \left[\frac{0}{v}\right] \right) \overset{(es)}{=} r[e(v)] \overset{r}{=} e[s(v)]$$

$(es_y) \Rightarrow (sq_y)$ By induction on $v$, using $(q)$.

$$(0) q \left[\frac{s(u)}{0}\right] \overset{(q, \perp)}{=} e[s(u)] \overset{r}{=} r[e(u)] \overset{(q, \perp)}{=} r \left( q \left[\frac{u}{0}\right] \right);$$

$$(s) q \left[\frac{s(u)}{s(v)}\right] \overset{(q, \perp)}{=} r \left( q \left[\frac{s(u)}{v}\right] \right) \overset{(es)}{=} r \left( r \left[\frac{u}{v}\right] \right) \overset{(q, \perp)}{=} r \left( q \left[\frac{u}{s(v)}\right] \right).$$

$(Vq_y) \Rightarrow (Kq_y)(0q_y) \ & \ (sq_y)$ yield, by induction on $x$, using $(q)$, commutativity of $q$ as follows:
Now, let us apply the criterion \((es_y)\) to functions addition \(ad\) and monus \(mn\) (in Section 4), which have (similar) value recursive formulations (cf. 4.2). In each case, we will proceed in two steps:

1. first, we instantiate the criterion \((es_y)\);
2. next, we check whether the instantiated criterion holds.

(ad) In the case of addition \(ad\) (cf. formulation (ad) in 4.1), we have

\[basis\ function: e(u) = \iota(u) ;\]
\[step\ function: r(w) = s(w).\]

1. So, the above criterion \((es_y)\) becomes

\((is_y): \forall w s([w]) \equiv s([w]), i.e. \forall w s(w) \equiv s(w).\)

2. Now, \(\forall w s(w) \equiv s(w)\) is identically satisfied.

Hence, addition \(ad\) is commutative: \(\forall x\forall y ad[y] \equiv ad[y]\)

(mn) In the case of monus \(mn\) (cf. formulation (mn) in 4.1), we have

\[basis\ function: e(u) = \iota(u) ;\]
\[step\ function: r(w) = pd(w).\]

1. So, the above criterion \((es_y)\) becomes

\((ipd_y): \forall w s([w]) \equiv pd([w]), i.e. \forall w s(w) \equiv pd(w).\)
2. Now, $\forall w \ s(w) \neq p(d(w)$ is not satisfied at $w = 0$.24

This fact provides a counterexample for the commutativity of monus $mn$, namely

$$-mn \begin{bmatrix} s(0) \\ 0 \end{bmatrix} \neq mn \begin{bmatrix} 0 \\ s(0) \end{bmatrix}.25$$

8.2. Conditions for associativity: value recursion

We will now characterize the associative value recursive binary operations.

Consider the following universal formulation of associativity of $q$:

$$(\forall q) \ \forall \forall x y z \ q \left( \begin{array}{c} x \\ y \\ z \end{array} \right) = q \left( \begin{array}{c} x \\ y \\ z \end{array} \right) \ \ \ \ a \ q (b \ q \ c) = (a \ q \ b) \ q \ c$$

Analogy with the case of commutativity suggests the following two conditions.

$(q_{e_q})$ Value at basis

$$\forall u v \ q \left( \begin{array}{c} u \\ v \end{array} \right) = e \left( \begin{array}{c} u \\ v \end{array} \right) \ \ \ \ a \ q \ e(b) = e(a \ q \ b)$$

This condition bridges the gap between the evaluations of $q \left( \begin{array}{c} u \\ 0 \end{array} \right)$ and $q \left( \begin{array}{c} u \\ 0 \end{array} \right)$.26

$(q_v)$ Value at step

$$\forall u v w \ q \left( \begin{array}{c} u \\ v \\ w \end{array} \right) = r \left( \begin{array}{c} u \\ v \\ w \end{array} \right) \ \ \ \ a r(q \ (b \ q \ c)) = r((a \ q \ b) \ q \ c)$$

This condition serves to reduce the gap between the evaluations of $q \left( \begin{array}{c} u \\ s(l(w)) \end{array} \right)$ and $q \left( \begin{array}{c} u \\ s(l(w)) \end{array} \right)$.

---

24 Indeed, $p(d(0) = 0$, and $-s(0) = 0$.

25 Indeed $\forall w s(0) = 0$, whereas $mn \begin{bmatrix} s(0) \\ 0 \end{bmatrix} = 0$.

26 Indeed $q \left( \begin{array}{c} u \\ 0 \end{array} \right) = q \left( \begin{array}{c} u \\ e(0) \end{array} \right)$ and $q \left( \begin{array}{c} u \\ 0 \end{array} \right) = e \left( \begin{array}{c} u \\ 0 \end{array} \right)$.

27 Indeed $q \left( \begin{array}{c} u \\ s(l(w)) \end{array} \right)$ and $q \left( \begin{array}{c} u \\ s(l(w)) \end{array} \right)$.
For instance, these two conditions lead to \( q\left(\frac{x}{y}\right)_{s(0)} \) as follows:

\[
q\left(\frac{x}{y}\right)_{s(0)} = q\left(\frac{x}{y}\right)_{s(0)} = q\left(\frac{x}{y}\right)_{s(0)} = q\left(\frac{x}{y}\right)_{s(0)}
\]

We can now see that these two conditions jointly characterize associativity.

For a binary operation \( q \) satisfying the value recursive formulation (q), the following conditions are equivalent.

\[(AQ) \forall x \forall y \forall z \quad q\left(\frac{x}{y}\right)_{z} = q\left(\frac{x}{y}\right)_{z} \quad \text{associativity of } q\]

(qer) Values at basis and at step

\[(q) \quad \text{Value at basis: } \forall u \forall v \quad q\left(\frac{u}{v}\right)_{e(v)} = e\left(\frac{u}{v}\right)\]

\[(qr) \quad \text{Value at step: } \forall u \forall v \forall w \quad q\left(\frac{u}{v}\right)_{r(q\left(\frac{v}{w}\right))} = r\left(\frac{u}{v}\right)_{q\left(\frac{v}{w}\right)}\]

Proof. We will show (qer) \(\Rightarrow\) (AQ) \& (AQ) \(\Rightarrow\) (qer).

(0) We show (qer) \(\Rightarrow\) (AQ) by induction on \( z \).

\[(0) \quad q\left(\frac{x}{y}\right)_{s(0)} = q\left(\frac{x}{y}\right)_{s(0)} = q\left(\frac{x}{y}\right)_{s(0)} = q\left(\frac{x}{y}\right)_{s(0)};\]

\[(s) \quad q\left(\frac{x}{y}\right)_{s(z)} = q\left(\frac{x}{y}\right)_{s(z)} = q\left(\frac{x}{y}\right)_{s(z)} = q\left(\frac{x}{y}\right)_{s(z)};\]
(1) We show \((Aq_x) \Rightarrow (qe_x) \& (Aq_x) \Rightarrow (qr_x)\).

\[(Aq_x) \Rightarrow (qe_x) : q\left[ e(v) \right] \stackrel{(q,\perp)}{=} q\left( q\left[ v \right]_{0} \right) \stackrel{(Aq)}{=} q\left( q\left[ v \right]_{0} \right) \stackrel{(q,\perp)}{=} e\left( q\left[ v \right]_{0} \right)\]

\[(Aq_x) \Rightarrow (qr_x) : q\left( r\left( q\left[ v \right]_{w} \right) \right) \stackrel{(q,\Rightarrow)}{=} q\left( q\left[ s(v) \right]_{w} \right) \stackrel{(Aq)}{=} q\left( q\left[ v \right]_{s(v)} \right) \stackrel{(q,\Rightarrow)}{=} r\left( q\left[ v \right]_{w} \right)\]

Now, let us apply these criteria to the functions addition \(ad\) and monus \(mn\) as in 8.1. Much as before, in each case, we will proceed in two steps:

1. first, we instantiate the criteria \((qe_x)\) and \((qr_x)\);
2. next, we check whether the instantiated criteria hold.

(ad) For addition \(ad\) (cf. formulation (ad) in 4.1), we have (cf. 8.1):

- **basis function**: \(e(u) = i(u)\);
- **step function**: \(r(w) = s(w)\).

So, the above conditions \((qe_x)\) and \((qr_x)\) become as follows.

\[(ad_x) : \forall u \forall v ad\left[ u \right]_{i(v)} \doteq e\left( ad\left[ v \right] \right) \text{ i.e., } \forall u \forall v ad\left[ v \right] \equiv ad\left[ u \right] \]

which is identically satisfied.

\[(ads_x) : \forall u \forall v \forall w ad\left( s\left( ad\left[ v \right]_{w} \right) \right) \equiv s\left( ad\left( ad\left[ v \right]_{w} \right) \right) \]

which follows from \((ad.\Rightarrow)\).

Thus, addition \(ad\) is associative: \(\forall x \forall y \forall z ad\left( ad\left[ y \right]_{z} \right) = ad\left( ad\left[ x \right]_{y} \right)\)

(mn) For monus \(mn\) (cf. formulation (mn) in 4.1), we have (cf. 8.1):

- **basis function**: \(e(u) = i(u)\);
- **step function**: \(r(w) = pd(w)\).
So, the above conditions \((q_e,v)\) and \((q_r,v)\) become as follows.

\[
(mn_u,v) : \forall u \forall v \; mn[u/v] = i(mn[v/u]), \text{ i.e. } \forall u \forall v \; mn[u/v] = mn[v/u]
\]

which is identically satisfied.

\[
(mn p_d,v) : \forall u \forall v \forall w \; mn[p_d(mn[v/w])] = p_d(mn[mn[v/w]]), \text{ i.e.,}
\]

\[
\forall u \forall v mn[p_d(u/v)] = p_d(mn[mn(u/v)]), \text{ i.e.,}
\]

by \((mn, \bot) : \forall u \forall v mn[p_d(u/v)] = p_d(mn(u/v))\)

\((w=0)\) At \(w=0\), this condition becomes

\[
\forall u \forall v mn[p_d(u/v)] = p_d(mn[u/v]), \text{ i.e.,}
\]

by \((pd, \bot)\) and \((mn, \bot) : \forall u \forall v mn[p_d(u/v)] = p_d(mn(u/v))\) which is not satisfied at \(u=s(0)\). 28

This fact provides a counterexample for the associativity of monus \(mn\), namely

\[
\neg mn(mn[0/s(0)]) = mn[mn[s(0)/s(0)]]. 29
\]

We can now summarize our discussion so far about commutativity and associativity of value recursive binary operations. First, we will summarize our criteria and the analyses of addition \(ad\) and monus \(mn\). Next, we will examine some further examples of value recursive binary operations.

The characterizations for a value recursive binary operation presented in this section serve, either to establish or to refute its commutativity, or

---

28 Indeed, \(pd[s(0)] \equiv 0\), and \(\neg s(0) \equiv 0\).

29 Indeed, \(mn(mn[s(0)/s(0)]) \equiv mn[mn[s(0)/s(0)] \equiv s(0), whereas mn(mn[s(0)/s(0)]) \equiv mn[mn[s(0)/s(0)] \equiv 0.\)
associativity. They rely only on the basis and step functions of the value recursive formulation. As such, they can be employed to analyze commutativity or associativity of other binary operations satisfying value recursive formulations.

Some examples of such binary operations, with their analyses, are as follows.

(adb) Addition of double, with \( \binom{a}{b} \mapsto a + 2 \cdot b \):

\[
\begin{align*}
\{adb[u,0]\} &= u \\
\{adb[u,s(v)]\} &= ss(adb[u,v])
\end{align*}
\]

\( \text{case } (\bot) \) \hspace{1cm} \text{(adb)}

This formulation (adb) has

\( \text{basis function: } \iota(u) = u; \)

\( \text{step function: } ss(w). \)

So, conditions (es_\text{v}), (qe_\text{v}) and (qr_\text{v}) become as follows

<table>
<thead>
<tr>
<th>(is_\text{v})</th>
<th>(adb_\text{v})</th>
<th>(qr_\text{v})</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \forall w ) \hspace{1cm} \iota(s(w))</td>
<td>( \forall u \forall v ) \hspace{1cm} adb[\iota(v)]</td>
<td>( \forall u \forall v \forall w ) \hspace{1cm} adb\left(ss(adb[\iota(v)])\right)</td>
</tr>
<tr>
<td>\cdot \bot</td>
<td>\cdot \bot</td>
<td>\cdot \bot</td>
</tr>
<tr>
<td>ss[\iota(w)]</td>
<td>i(adb[u])</td>
<td>ss(abd[\iota(v)])</td>
</tr>
</tbody>
</table>

Now, conditions (is_\text{v}) and (qr_\text{v}) fail.

Hence, addition of double adb is non-commutative and non-associative.

(dba) Double of addition, with \( \binom{a}{b} \mapsto 2 \cdot (a + b) \):

\[
\begin{align*}
\{dba[u,0]\} &= db(u) \\
\{dba[u,s(v)]\} &= ss(bda[u,v])
\end{align*}
\]

\( \text{case } (\bot) \) \hspace{1cm} \text{(adb)}

This formulation (dba) has

\( \text{basis function: } db(u); \)

\( \text{step function: } ss(w) \)
So, conditions \((es_v)\), \((qe_v)\) and \((qr_v)\) become as follows

\[
\begin{array}{ccc}
(dbs_v) & (dba \, db_v) & (dba \, ss_v) \\
\forall w \quad db[s(w)] & \forall u \forall v \quad dba[db(v)] & \forall u \forall v \forall w \quad dba(ss(dba[db(w)])) \\
\cdot \circ & \cdot \circ & \cdot \circ \\
s\, ss[db(w)] & \, db(dba[u]) & \, ss(dba(dba[w]))
\end{array}
\]

Now, condition \((dbs_v)\) holds, whereas conditions \((dba \, db_v)\) and \((dba \, ss_v)\) fail. Hence, double of addition \(dba\) is commutative and non-associative.

\((γ)\) Left projection, with \((\frac{a}{b}) \mapsto a:\)

\[
\begin{align*}
\{γ[u, 0] & = u \quad \text{case (⊥)} \\
\{γ[u, s(v)] & = u \quad \text{case (⇒)} \quad (γ)
\end{align*}
\]

This formulation \((γ)\) has

- basis function: \(ι(u) = u;\)
- step function: \(ι(w) = w.\)

So, conditions \((es_v)\), \((qe_v)\) and \((qr_v)\) become as follows

\[
\begin{array}{ccc}
(ιs_v) & (γ \, ι_v) & γ \, ι_v \\
\forall w \quad ι[s(w)] & \forall u \forall v \quad γ[ι(v)] & \forall u \forall v \forall w \quad γ(ι(γ[ι[w]])) \\
\cdot \circ & \cdot \circ & \cdot \circ \\
ι[ι(w)] & ι(γ[u]) & ι(γ(γ[u]))
\end{array}
\]

Now, condition \((ιs_v)\) fails, whereas conditions \((γ \, ι_v)\) and \((γ \, ι_v)\) both hold. Hence, left projection \(γ\) is non-commutative and associative.
(δ) Right projection, with \( \left( \frac{a}{b} \right) \mapsto b \):

\[
\begin{align*}
\delta [u, 0] & \triangleq 0 \\
\delta [u, s(v)] & \triangleq s(\delta [u, v])
\end{align*}
\]

\textit{case (1)} \quad (δ)

This formulation (δ) has

\textit{basis function: } \zeta(u) = 0;

\textit{step function: } s(w).

So, conditions (es), (qe), and (qr) become as follows

<table>
<thead>
<tr>
<th>(( \zeta_s ))</th>
<th>(( \delta \zeta ))</th>
<th>(( \xi_s ))</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \forall \forall \forall \forall )</td>
<td>( \forall u \forall \forall )</td>
<td>( \forall \forall \forall \forall \forall )</td>
</tr>
<tr>
<td>( \zeta[s(w)] )</td>
<td>( \delta \left[ \frac{u}{\zeta(v)} \right] )</td>
<td>( \delta \left( \frac{s(\delta \left[ \frac{v}{w} \right])}{u} \right) )</td>
</tr>
<tr>
<td>( \vdash )</td>
<td>( \vdash )</td>
<td>( \vdash )</td>
</tr>
<tr>
<td>( s[\zeta(w)] )</td>
<td>( \zeta \left( \frac{u}{v} \right) )</td>
<td>( s \left( \frac{\delta \left[ \frac{v}{w} \right]}{u} \right) )</td>
</tr>
</tbody>
</table>

Now, condition (\( \zeta_s \)) fails, whereas conditions (\( \delta \zeta \)) and (\( \xi_s \)) both hold.

Hence, right projection \( \delta \) is non-commutative and associative.

In the next section, we shall characterize commutativity and associativity of a binary operation satisfying a simple recursive formulation.

9. General Conditions: simple recursion

We will now examine some general conditions for two properties of a simple recursive binary operation (cf. 4.2 in Section 4).

Consider a binary function with the following universal simple recursive formulation:
The God-given Naturals: Induction and Recursion

O que nos faz pensar, Rio de Janeiro, v.29, n.49, p.115-156, jul.-dez.2021

This formulation \( \hat{m} \) has unary basis function \( \hat{p}(u) \) and binary step function \( \check{t}(\cdot) \).

We wish to establish conditions for some properties of such a binary operation \( \hat{m} \). We will examine conditions for commutativity (in 9.1) and for associativity (in 9.2).

9.1. Conditions for commutativity: simple recursion

We will now characterize the commutative simple recursive binary operations.

Consider the following universal formulation of commutativity of:

\[
(\forall m \forall x y) m[y] = m[x] \quad a \hat{m} b = b \hat{m} a
\]

An analogy with the case of value recursion suggests the following three properties.

\( (V m \forall) \) Values of \( \hat{m} \) at left zero and at left successor

\[
(0m \forall) \forall v \hat{m}[v] = \hat{p}[v] \quad \hat{m} \text{ at left } 0: 0 \hat{m} b = \hat{p}(b)
\]

\[
(sm \forall) \forall u \forall v \hat{m}[s(u)] = \check{t}(\hat{m}[s(v)]) \quad \hat{m} \text{ at left } s: s(a) \hat{m} b = b \check{t}(a \hat{m} b)
\]

\[
(p s \forall) \forall w \hat{p}[s(w)] = \check{t}(0) \quad \text{Basis } \hat{p} \text{ at successor: } \hat{p}(s(b)) = 0 \check{t}(b)
\]

Let us see some examples of how these conditions are used to establish commutativity.

- Conditions \( (V m \forall) \) lead to \( \hat{m} [y] = m[y] \) as follows:

\[
\hat{m} [s(0)] = m[y] = m[y] \quad (0 \hat{m}) \quad (m \forall) \quad (\check{t}(\cdot)) \quad (\hat{p}(\cdot)) \quad (\check{t}(\cdot) \uparrow) \quad (\hat{m} \check{t}(\cdot)) \quad (\hat{m} \check{t}(\cdot)) \quad (m \check{t}(\cdot)) \quad (\hat{m} \check{t}(\cdot)) \quad (m \check{t}(\cdot))
\]
- Conditions \((p's_v)\) lead to \(\hat{m} \left[ s(0) \right]_0 \overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}}}}}}\) as follows:

\[
\hat{m} \left[ s(0) \right]_0 \overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(0) \right]_0}}}}}}\]

We can now see that we have two alternative characterizations for commutativity.

For a binary operation \(q\) satisfying the value recursive formulation, the following conditions are equivalent.

\[
(K\hat{m}_v) \forall x \forall y \hat{m} \left[ x \right]_y \overset{m_1 \equiv \hat{m} \left[ x \right]_y}{\overset{m_1 \equiv \hat{m} \left[ x \right]_y}{\overset{m_1 \equiv \hat{m} \left[ x \right]_y}{\overset{m_1 \equiv \hat{m} \left[ x \right]_y}{\overset{m_1 \equiv \hat{m} \left[ x \right]_y}{\overset{m_1 \equiv \hat{m} \left[ x \right]_y}}}}}}
\]

\[
\text{commutativity of } \hat{m}
\]

\[
(V\hat{m}_v) \forall v \forall \hat{m} \left[ 0 \right]_v \overset{m_1 \equiv \hat{m} \left[ 0 \right]_v}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_v}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_v}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_v}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_v}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_v}}}}}}
\]

\[
\hat{p}[s(w)] \overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}}}}}}
\]

\[
\text{basis at successor}
\]

Proof: We will show \((K\hat{m}_v) \Rightarrow (p's_v) \Rightarrow (V\hat{m}_v) \Rightarrow (K\hat{m}_v)\)

\((K\hat{m}_v) \Rightarrow (p's_v)\) Commutativity of \(\hat{m}\) yields, by \((\hat{m})\) \((p's)\) as follows:

\[
\hat{p}[s(w)] \overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(w) \right]_0}}}}}}
\]

\[
(p's) \Rightarrow (V\hat{m}_v) \text{ We show } (p's) \Rightarrow (0\hat{m}_v) \text{ and } (p's) \Rightarrow (s\hat{m}_v), \text{ both by induction on } v, \text{ using } (\hat{m}).
\]

\[
(p's) \Rightarrow (0\hat{m}_v) \text{ By induction on } v, \text{ using } (\hat{m}).
\]

\[
(0) \hat{m} \left[ 0 \right]_0 \overset{m_1 \equiv \hat{m} \left[ 0 \right]_0}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_0}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_0}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_0}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_0}{\overset{m_1 \equiv \hat{m} \left[ 0 \right]_0}}}}}}
\]

\[
(p's) \Rightarrow (s\hat{m}_v) \text{ By induction on } v, \text{ using } (\hat{m}).
\]

\[
(0) \hat{m} \left[ u \right]_0 \overset{m_1 \equiv \hat{m} \left[ u \right]_0}{\overset{m_1 \equiv \hat{m} \left[ u \right]_0}{\overset{m_1 \equiv \hat{m} \left[ u \right]_0}{\overset{m_1 \equiv \hat{m} \left[ u \right]_0}{\overset{m_1 \equiv \hat{m} \left[ u \right]_0}{\overset{m_1 \equiv \hat{m} \left[ u \right]_0}}}}}}
\]

\[
(s) \hat{m} \left[ s(u) \right]_v \overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}}}}}}
\]

\[
(p's) \Rightarrow (s\hat{m}_v) \text{ By induction on } v, \text{ using } (\hat{m}).
\]

\[
(0) \hat{m} \left[ s(u) \right]_0 \overset{m_1 \equiv \hat{m} \left[ s(u) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_0}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_0}}}}}}
\]

\[
(s) \hat{m} \left[ s(u) \right]_v \overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}{\overset{m_1 \equiv \hat{m} \left[ s(u) \right]_v}}}}}}
\]
(V fn) ⇒ (K fn) & (sm fn) yield, by induction on x, using (fm), commutativity of (fm) as follows:

\[(0) \quad fn \left[ y \right] = \delta(0n) \equiv \delta(y) = fn \left[ 0 \right]; \]

\[(s) \quad fn \left[ s(x) \right] = \delta \left( \frac{y}{m} \left[ x \right] \right) = \delta \left( \frac{y}{m} \left[ y \right] \right) = fn \left[ s(x) \right]. \]

Now, let us apply the criterion (ps fn) to functions multiplication mt and exponentiation pw (in Section 4), which have (similar) value recursive formulations. As before, in each case, we will proceed in two steps as follows:

1. first, we instantiate the criterion (ps fn);
2. next, we check whether the instantiated criterion holds.

(mt) In the case of multiplication mt (cf. formulation (mt) in 4.1), we have:

basis function: \( \delta(u) = \xi(u) \);
step function: \( \tau \left( \frac{u}{w} \right) = ad \left( \frac{u}{w} \right) \)

So, the above criterion (ps fn) becomes

\[(\xi s): \forall w \quad \xi[s(w)] = ad \left( \frac{0}{\xi[w]} \right), \text{i.e. } 0 = ad \left( \frac{0}{0} \right). \]

Now, \( 0 = ad \left( \frac{0}{0} \right) \) follows from (ad⊥)

Hence, multiplication mt is commutative: \( \forall x \forall y \quad mt \left[ \frac{x}{y} \right] = \left[ Y \right]. \)

(pw) In the case of exponentiation pw (cf. formulation (pw) in 4.1), we have:

basis function: \( \delta(u) = v(u) \);
step function: \( \tau \left( \frac{u}{w} \right) = mt \left( \frac{u}{w} \right) \)

1. So, the above criterion (ps fn) becomes

\[(u s): \forall w \quad v[s(w)] = \left( \frac{0}{v[w]} \right), \text{i.e. } s(0) = mt \left( \frac{0}{s(0)} \right). \]
2. Now, \( s(0) = mt \left( \begin{array}{c} 0 \\ s(0) \end{array} \right) \) is not satisfied.\(^{30}\)

This fact provides a counterexample for the commutativity exponentiation \(pw\), namely

\[-pw \left[ \begin{array}{c} s(0) \\ 0 \end{array} \right] = pw \left[ \begin{array}{c} 0 \\ s(0) \end{array} \right].\(^{31}\)

9.2. Conditions for associativity: simple recursion

We will now characterize the associative value recursive binary operations. Consider the following universal formulation of associativity of \(\hat{m}\):

\[ (A\hat{m}) \forall x \forall y \forall z \; \hat{m} \left( \begin{array}{c} x \\ m \left[ \begin{array}{c} y \\ z \end{array} \right] \end{array} \right) = \hat{m} \left( \begin{array}{c} x \\ \hat{m} \left[ \begin{array}{c} y \\ z \end{array} \right] \end{array} \right) \quad a \; \hat{m}(b \; \hat{m} \; c) = (a \; \hat{m} \; b) \; \hat{m} \; c

Analogy with the case of value recursion suggests the following two properties.

\[ (\hat{m} \; \hat{p}_v) \; \text{Value at basis} \quad a \; \hat{m} \; \hat{p}(b) = \hat{p}(a \; \hat{m} \; b) \]

\[ \forall u \forall v \; \hat{m} \left[ \begin{array}{c} v \\ \hat{p}(v) \end{array} \right] = \hat{p} \left( \hat{m} \left[ \begin{array}{c} v \\ v \end{array} \right] \right) \]

This condition bridges the gap between the evaluations of \(\hat{m} \left( \begin{array}{c} u \\ \hat{m} \left[ \begin{array}{c} v \\ 0 \end{array} \right] \end{array} \right)\) and \(\hat{m} \left( \hat{m} \left[ \begin{array}{c} v \\ 0 \end{array} \right] \right)\).\(^{32}\)

\[ (\hat{m} \; \hat{t}_v) \; \text{Value at step} \quad a \; \hat{m}[b \; \hat{t}(b \; \hat{m} \; c)] = (a \; \hat{m} \; b) \; \hat{t}[a \; \hat{m} \; b \; \hat{m} \; c] \]

\[ \forall x \forall y \forall z \; \hat{m} \left( \begin{array}{c} u \\ \hat{m} \left[ \begin{array}{c} v \\ w \end{array} \right] \end{array} \right) = \hat{t} \left( \begin{array}{c} \hat{m} \left[ \begin{array}{c} u \\ v \end{array} \right] \\ \hat{m} \left[ \begin{array}{c} v \\ w \end{array} \right] \end{array} \right) \]

---

30 Indeed, \(mt \left( \begin{array}{c} 0 \\ s(0) \end{array} \right) = 0\), and \(s(0) = 0\).

31 Indeed, \(pw \left[ \begin{array}{c} s(0) \\ 0 \end{array} \right] = s(0)\), whereas \(pw \left[ \begin{array}{c} 0 \\ s(0) \end{array} \right] = 0\).

32 Indeed, \(\hat{m} \left( \begin{array}{c} u \\ \hat{m} \left[ \begin{array}{c} v \\ 0 \end{array} \right] \end{array} \right) = \hat{m} \left( \begin{array}{c} u \\ \hat{p}(v) \end{array} \right)\) and \(\hat{m} \left( \begin{array}{c} u \\ \hat{m} \left[ \begin{array}{c} v \\ 0 \end{array} \right] \end{array} \right) = \hat{p} \left( \hat{m} \left[ \begin{array}{c} u \\ v \end{array} \right] \right)\).
This condition serves to reduce the gap between the evaluations of \( \hat{m} \left( \hat{m} \left[ \frac{u}{v} \right]_{s(w)} \right) \) and \( \hat{m} \left( \hat{m} \left[ \frac{u}{v} \right]_{s(w)} \right) \)\(^{33}\).

For instance, these two conditions lead to \( \hat{m} \left( \hat{m} \left[ \frac{x}{y} \right]_{s(0)} \right) \) as follows:

\[
\hat{m} \left( \hat{m} \left[ \frac{x}{y} \right]_{s(0)} \right) \overset{(\hat{m}_{\bot})}{=} q \left( \hat{t} \left( \hat{m} \left[ \frac{x}{0} \right] \right) \right) \overset{(\hat{m}_{\top})}{=} \hat{t} \left( \hat{m} \left[ \frac{u}{v} \right]_{s(0)} \right) \overset{(\hat{m}_{\bot})}{=} \hat{m} \left( \hat{m} \left[ \frac{u}{v} \right] \right) \frac{x}{y}\]

\[
\hat{t} \left( \hat{m} \left[ \frac{x}{y} \right] \right) \overset{(\hat{m}_{\top})}{=} \hat{t} \left( \hat{m} \left[ \frac{x}{y} \right] \right) \overset{(\hat{m}_{\bot})}{=} \hat{m} \left( \hat{m} \left[ \frac{x}{y} \right] \right) \frac{x}{y}\]

We can now see that these two conditions jointly characterize associativity.

For a binary operation satisfying the simple recursive formulation \( \hat{m} \), the following conditions are equivalent.

\[
(A\hat{m}_{\circ}) \forall x \forall y \forall z \hat{m} \left( \hat{m} \left[ \frac{x}{z} \right] \right) \overset{\hat{m}_{\circ}}{=} \hat{m} \left( \hat{m} \left[ \frac{y}{z} \right] \right) \quad \text{associativity of } \hat{m}
\]

\( (\hat{m} \hat{p} \hat{t} \circ) \) Values at basis and at step

\[
(\hat{m} \hat{p} \hat{t} \circ) \text{ Values at basis: } \forall u \forall v \hat{m} \left[ \frac{u}{v} \right]_{\hat{m} \left[ \hat{p} \left( \frac{v}{y} \right) \right]} \overset{\hat{m}}{=} \hat{p} \left( \hat{m} \left[ \frac{u}{v} \right] \right)
\]

\[
(\hat{m} \hat{t} \circ) \text{ Values at step: } \forall u \forall v \forall w \hat{m} \left( \hat{t} \left( \hat{m} \left[ \frac{v}{w} \right] \right) \right) \overset{\hat{m}}{=} \hat{t} \left( \hat{m} \left[ \frac{u}{v} \right] \right)
\]

Proof. We will show \( (\hat{m} \hat{p} \hat{t} \circ) \Rightarrow (A\hat{m}_{\circ}) \) & \( (A\hat{m}_{\circ}) \Rightarrow (\hat{m} \hat{p} \hat{t} \circ) \)

(\( \check{\implies} \)) We show \( (\hat{m} \hat{p} \hat{t} \circ) \Rightarrow (A\hat{m}_{\circ}) \) by induction on \( z \).

\[
(0) \hat{m} \left( \hat{m} \left[ \frac{x}{y} \right] \right) \overset{(\hat{m}_{\bot})}{=} \hat{m} \left( \hat{m} \left[ \frac{x}{y} \right] \right) \overset{(\hat{m}_{\top})}{=} \hat{p} \left( \hat{m} \left[ \frac{x}{y} \right] \right) \overset{(\hat{m}_{\bot})}{=} \hat{m} \left( \hat{m} \left[ \frac{x}{y} \right] \right)
\]

\[^{33}\text{Indeed, } \hat{m} \left( \hat{m} \left[ \frac{u}{v} \right] \right) \overset{(\hat{m}_{\circ})}{=} \hat{t} \left( \hat{m} \left[ \frac{u}{v} \right] \right) \text{ and } \hat{m} \left( \hat{m} \left[ \frac{u}{v} \right] \right) \overset{(\hat{m}_{\circ})}{=} \hat{t} \left( \hat{m} \left[ \frac{u}{v} \right] \right) \]
We show $(Am) \Rightarrow (\hat{m} \hat{p})$ & $(Am) \Rightarrow (\hat{m} \hat{t})$

Now, let us apply these criteria to the functions multiplication $mt$ and exponentiation $pw$ used as examples in 9.1. Much as before, in each case, we will proceed in two steps:

1. first, we instantiate the criteria $(\hat{m} \hat{p})$ and $(\hat{m} \hat{t})$;
2. next, we check whether the instantiated criteria hold.

(mt) For multiplication $mt$ (cf. formulation (mt) in 4.1), we have (cf. 9.1):

basis function: $\hat{p}(u) = \zeta(u)$; step function: $\hat{t}\left(\begin{bmatrix} u \\ w \end{bmatrix}\right) = ad\left(\begin{bmatrix} u \\ w \end{bmatrix}\right)$

So, the above conditions $(\hat{m} \hat{p})$ and $(\hat{m} \hat{t})$ become as follows.

$(mt\zeta): \forall u \forall v \; mt\left[\begin{bmatrix} u \\ \zeta(v) \end{bmatrix}\right] = \zeta\left(mt\left[\begin{bmatrix} u \\ v \end{bmatrix}\right]\right)$, i.e. $\forall u \; mt\left[\begin{bmatrix} u \\ 0 \end{bmatrix}\right] = 0;$
which follows from \((mt⊥)\).

\[
(mt_{ad⊥}) : \forall u \forall v \forall w \quad mt \left( \left( \begin{array}{c} u \\ v \\ w \end{array} \right) \right) = ad \left( \begin{array}{c} mt\\ u \\ w \end{array} \right)
\]

which follows from distributivity.

\((pw)\) For exponentiation \(pw\) (cf. formulation \((pw)\) in 4.1), we have (cf. 9.1):

- **basis function**: \(\hat{p}(u) = v(u)\);  
- **step function**: \(t \left( \begin{array}{c} u \\ w \end{array} \right) = mt \left( \begin{array}{c} u \\ w \end{array} \right)\)

So, the above conditions \((m\hat{p})\) and \((m\hat{t})\) become as follows.

\[
(pw_{uv}) : \forall u \forall v \quad pw \left( \begin{array}{c} u \\ v \\ w \end{array} \right) \not= v \left( \begin{array}{c} pw\\ u \\ v \\ w \end{array} \right), \text{i.e.}, \forall u \quad pw \left( \begin{array}{c} u \\ s(0) \\ w \end{array} \right) \not= s(0);
\]

which is *not* satisfied at \(u = 0\) \(^{34}\)

This fact provides a counter-example for the associativity of exponentiation \(pw\), namely \(\neg pw \left( \begin{array}{c} 0 \\ pw \\ 0 \end{array} \right) \not= pw \left( \begin{array}{c} pw\\ 0 \\ 0 \end{array} \right)\) \(^{35}\)

\[
(pw_{mtuv}) : \forall u \forall v \forall w \quad pw \left( \begin{array}{c} u \\ v \\ w \end{array} \right) \not= pw \left( \begin{array}{c} pw\\ u \\ v \\ w \end{array} \right), \text{i.e.}, \forall u \quad pw \left( \begin{array}{c} u \\ pw \\ s(0) \end{array} \right) \not= pw \left( \begin{array}{c} pw\\ u \\ s(0) \end{array} \right) \not= s(0);
\]

which is *not* satisfied at \(u = ss(0), v = s(0), w = 0\) \(^{36}\)

---

\(^{34}\) Indeed \(pw \left( \begin{array}{c} 0 \\ s(0) \\ 0 \end{array} \right) \not= 0\).

\(^{35}\) Indeed \(pw \left( \begin{array}{c} 0 \\ pw \\ 0 \end{array} \right) \not= pw \left( \begin{array}{c} 0 \\ pw \\ 0 \end{array} \right) \not= 0\) whereas \(pw \left( \begin{array}{c} pw\\ 0 \\ 0 \end{array} \right) \not= pw \left( \begin{array}{c} s(0) \\ 0 \\ 0 \end{array} \right) = s(0)\).

\(^{36}\) Indeed \(pw \left( \begin{array}{c} s^2(0) \\ s(0) \\ 0 \end{array} \right) \not= pw \left( \begin{array}{c} s^2(0) \\ s(0) \\ 0 \end{array} \right) \not= s(0)\) whereas

\[
mt \left( \begin{array}{c} pw\\ s(0) \\ s(0) \\ 0 \end{array} \right) \not= mt \left( \begin{array}{c} pw\\ s^2(0) \\ 0 \end{array} \right) = s^2(0)\) whereas

\[
mt \left( \begin{array}{c} pw\\ s^2(0) \\ 0 \\ 0 \end{array} \right) \not= mt \left( \begin{array}{c} s^2(0) \\ s(0) \\ 0 \end{array} \right) = s^2(0)\).
This fact provides yet another counterexample for the associativity of exponentiation $p^w$, namely

$$\neg p^w \left( \begin{array}{c} \text{ss(0)} \\ \text{s(0)} \end{array} \right) = p^w \left( \begin{array}{c} \text{ss(0)} \\ \text{s(0)} \end{array} \right)$$
