#### Abstract

Although the Four Colour Theorem is passé, we give an elementary pre-formal proof that transparently illustrates why four colours suffice to chromatically differentiate any set of contiguous, simply connected and bounded, planar spaces; by showing that there is no minimal 4 -coloured planar map $\mathcal{M}$. Keywords. contiguous area, four colour theorem, 4 CT , planar map, pre-formal proof, simply connected. 2010 Mathematics Subject Classification. 05C15 DECLARATIONS • Funding: Not applicable - Conflicts of interest/Competing interests: Not applicable • Availability of data and material: Not applicable - Code availability: Not applicable - Authors' contributions: Not applicable

## 1. Introduction

Although the Four Colour Theorem is considered passé (see §1.A.), we give an elementary pre-formal proof that transparently illustrates why four colours suffice to chromatically differentiate any set of contiguous, simply connected and bounded, planar spaces by showing that:
(1) If, for some natural numbers $m, n$, every planar map of less than $m+n$ contiguous, simply connected and bounded, areas can be 4-coloured;
(2) And, there is a minimal 4-coloured planar map $\mathcal{M}$, of $m+n$ such areas, where creation of an additional contiguous, simply connected and bounded, area $C$ within $\mathcal{M}$ yields a map $\mathcal{C}$ which necessitates that $C$ require a $5^{t h}$ colour;
(3) Then:
(a) If $A_{m}$ is a set of $m$ contiguous, simply connected, and bounded areas of $\mathcal{C}$, none of which shares a non-zero boundary segment with $C$; and $B_{n}$ is a set of $n$ contiguous, simply connected and bounded, areas of $\mathcal{C}$, some of which share at least one, non-zero, boundary segment with $C$, then $m=0$;
(b) No two areas $b_{n, i}, b_{n, j}$ of $B_{n}$ can share two, distinctly separated, non-zero boundary segments;
(c) No two areas $b_{n, i}, b_{n, j}$ of $B_{n}$ can share a non-zero boundary segment that has no point in common with $C$ if each area of $B_{n}$ abuts the area $C$ only once;
(d) Some area $b_{n, i}$ of $B_{n}$ must share at least two, distinctly separated, non-zero, boundary segments with $C$;
(e) No area $b_{n, i}$ of $B_{n}$ can share two, distinctly separated, non-zero boundary segments with $C$.

We conclude that there is no minimal 4-coloured planar map $\mathcal{M}$.

## 1.A. A historical perspective

It would probably be a fair assessment that the mathematical significance of any new proof of the Four Colour Theorem 4CT continues to be perceived as lying not in any ensuing theoretical or practical utility of the Theorem per se, but in whether the proof can address the philosophically 'unsatisfying', and occasionally 'despairing' (see [Tym79]; [Sw80]; [Gnt08], [Cl01]) lack of, mathematical 'insight', 'simplicity' and 'elegance' in currently known proofs of the Theorem (eg. [AH77], [AHK77], [RSST], [Gnt08]) -an insight and simplicity this investigation seeks in a pre-formal ${ }^{1}$ proof of 4 CT .

For instance we note - amongst others-some candid comments from Robertson, Sanders, Seymour, and Thomas's 1995-dated (apparently pre-publication) web-survey ${ }^{2}$ of their proof [RSST]:
"The Four Color Problem dates back to 1852 when Francis Guthrie, while trying to color the map of counties of England noticed that four colors sufficed. He asked his brother Frederick if it was true that any map can be colored using four colors in such a way that adjacent regions (i.e. those sharing a common boundary segment, not just a point) receive different colors. Frederick Guthrie then communicated the conjecture to DeMorgan. The first printed reference is due to Cayley in 1878 ([Cay79]).

The next major contribution came from Birkhoff whose work allowed Franklin in 1922 to prove that the four color conjecture is true for maps with at most 25 regions. It was also used by other mathematicians to make various forms of progress on the four color problem. We should specifically mention Heesch who developed the two main ingredients needed for the ultimate proof - reducibility and discharging. While the concept of reducibility was studied by other researchers as well, it appears that the idea of discharging, crucial for the unavoidability part of the proof, is due to Heesch, and that it was he who conjectured that a suitable development of this method would solve the Four Color Problem.

This was confirmed by Appel and Haken in 1976, when they published their proof of the Four Color Theorem [1.2] (sic).

Why a new proof?
There are two reasons why the Appel-Haken proof is not completely satisfactory.

- Part of the Appel-Haken proof uses a computer, and cannot be verified by hand, and
- even the part that is supposedly hand-checkable is extraordinarily complicated and tedious, and as far as we know, no one has verified it in its entirety."
... Thomas et al: [RSSp], Pre-publication web survey.

#### Abstract

"It has been known since 1913 that every minimal counterexample to the Four Color Theorem is an internally six-connected triangulation. In the second part of the proof, published in [4, p. 432], Robertson et al. proved that at least one of the 633 configurations appears in every internally six-connected planar triangulation. This condition is called "unavoidability," and uses the discharging method, first suggested by Heesch. Here, the proof differs from that of Appel and Haken in that it relies far less on computer calculation. Nevertheless, parts of the proof still cannot be verified by a human. The search continues for a computer-free proof of the Four Color Theorem." ... Brun: [Bru02], §1. Introduction (Article for undergraduates)

"Being the first ever proof to be achieved with substantial help of a computer, it has raised questions to what a proof really is. Many mathematicians remain sceptical about the nature of this proof due to the involvement of a computer. With the possibility of a computing error, they do not feel comfortable relying on a machine to do their work as they would be if it were a simple pen-and-paper proof.

The controversy lies not so much on whether or not the proof is valid but rather whether the proof is a valid proof. To mathematicians, it is as important to understand why something is correct as it is finding the solution. They hate that there is no way of knowing how a computer reasons. Since a computer runs programs as they are fed into it, designed to tackle a problem in a particular way, it is likely they will return what the programmer wants to find leaving out any other possible outcomes outside the bracket.

[^0]Many mathematicians continue to search for a better proof to the problem. They prefer to think that the Four Colour problem has not been solved and that one day someone will come up with a simple completely hand checkable proof to the problem."
...Nanjwenge: [Nnj18], Chapter 8, Discussion (Student Thesis).
"The heavy reliance on computers in Appel and Haken's proof was immediately a topic of discussion and concern in the mathematical community. The issue was the fact that no individual could check the proof; of special concern was the reductibility [sic] part of the proof because the details were "hidden" inside the computer. Though it isn't so much the validity of the result, but the understanding of the proof. Appel himself commented: "...there were people who said, 'This is terrible mathematics, because mathematics should be clean and elegant,' and I would agree. It would be nicer to have clean and elegant proofs." See page 222 of Wilson."

## 2. A pre-formal proof of the 4 -Colour Theorem

Proposition: No planar map requires more than four colours.

Fig. 1

## Definitions

(1) Consider the surface of the hemisphere (planar map $\mathcal{C}$ ) in Fig. 1 where:
(a) $A_{m}$ denotes a region of $m$ contiguous, simply connected and bounded, surface areas $a_{m, 1}, a_{m, 2}, \ldots, a_{m, m}$, none of which shares a non-zero boundary segment with the contiguous, simply connected, surface area $C$ (as indicated by the red barrier which, however, is not to be treated as a boundary of the region $A_{m}$ );
(b) $B_{n}$ denotes a region of $n$ contiguous, simply connected and bounded, surface areas $b_{n, 1}, b_{n, 2}$, $\ldots, b_{n, n}$, some of which share at least one non-zero boundary segment $c_{n, i}$ with $C$. In other words, for each $1 \leq i \leq r, c_{n, i}=b_{n, j}$ for some $1 \leq j \leq n$;
(c) $C$ is a single contiguous, simply connected and bounded, area created by annexing one or more contiguous, simply connected, portions of each area $c_{n, i}$ in the region $B_{n}$;
(d) $N$ is treated as an orientation pole of the hemisphere.

## Hypothesis

(2) Since four colours suffice for maps with fewer than 25 regions, we assume the existence of some $m, n$ which define a minimal configuration of the region $\left\{A_{m}+B_{n}+C\right\}$ where:
(a) any configuration of $p$ contiguous, simply connected and bounded, areas can be 4-coloured if $p \leq m+n$, where $p, m, n \in \mathbb{N}$, and $m+n \geq 25$;
(b) any configuration of the $m+n$ contiguous, simply connected and bounded, areas of the region $\left\{A_{m}+B_{n}\right\}$ can be 4-coloured (before the creation of $C$ by annexing some portions from each area $c_{n, i}$ of $B_{n}$ );
(c) the region $\left\{A_{m}+B_{n}+C\right\}$ in the planar map $\mathcal{C}$ is a specific configuration of $m+n+$ 1 contiguous, simply connected and bounded, areas that cannot be 4-coloured (by the minimality condition); whence the area $C$ necessarily requires a $5^{\text {th }}$ colour.

Lemma (Annexation): Creating additional areas in $\mathcal{C}$ does not eliminate the need for a 5 'th colour.
(3) Note that once the area $C$ is created, creating additional areas does not eliminate the need for a $5^{\text {th }}$ colour, since:
(a) If a new area is created strictly within the region $\left\{A_{m}+B_{n}\right\}$, the $5^{t h}$ colour is necessitated for the newly created area by the minimality assumption.
(b) If the area $C$ is sub-divided into the two areas $C_{1}$ and $C_{2}$, then either one can be absorbed back into the original areas in $B_{n}$ from which it was formed by annexation, reducing the configuration again to a minimal one; thus necessitating the $5^{\text {th }}$ colour.

Lemma (a): If $A_{m}$ is a set of $m$ contiguous, simply connected, and bounded areas of $\mathcal{C}$, none of which shares a non-zero boundary segment with $C$; and $B_{n}$ is a set of $n$ contiguous, simply connected and bounded, areas of $\mathcal{C}$, some of which share at least one, non-zero, boundary segment with $C$, then $m=0$.
(4) Consider, now, the mirror image of Fig.1, with mirrored regions $A_{m}^{\prime}, B_{n}^{\prime}$, area $C^{\prime}$, and orientation pole $S$ (Fig.2).

Fig. 2
(5) By our hypothesis that the region $\left\{A_{m}+B_{n}\right\}$ (ergo its mirror image $\left\{A_{m}^{\prime}+B_{n}^{\prime}\right\}$ ) can be 4coloured, joining the two halves into a sphere, where each area of the region $B_{n}$ is aligned with its mirror image, would extinguish both $C$ and $C^{\prime}$, yielding a 4-coloured configuration of at least $n+2 m$ contiguous, simply connected and bounded, areas forming the region $\left\{A_{m}+B_{n}+B_{n}^{\prime}+A_{m}^{\prime}\right\}$ (now on the surface of the sphere formed by melding the two hemispheres).
(6) However, creation of $\left\{A_{m}+B_{n}+B_{n}^{\prime}+A_{m}^{\prime}\right\}$ from $\left\{A_{m}+B_{n}\right\}$, initially by annexing areas of $\mathcal{M}$ to form $\mathcal{C}$, and thereafter of $\mathcal{C}$ to form successor maps, would contradict the Annexation Lemma if $A_{m}$ contained at least one area which does not share a non-zero boundary segment with $C$.
(7) Hence the region $A_{m}$ is empty under minimality, and $m=0$. Moreover, by repeated reasoning, the region $B_{n}$ cannot contain any area which does not share a non-zero boundary segment with $C$; whence each area of the region $B_{n}$ abuts the area $C$ at least once.

Lemma (b) No two areas $b_{n, i}, b_{n, j}$ of $B_{n}$ can share two, distinctly separated, non-zero boundary segments.
(8) If region $A_{m}$ is empty, and each area of region $B_{n}$ abuts the area $C$ at least once, then:
(a) no two areas $b_{n, i}$ and $b_{n, j}$ of region $B_{n}$ can share two, distinctly separated, non-zero boundary segments,
(b) since the $l$ areas of the region, say $A_{l}(l>0)$, enclosed by such boundary segments of the areas $b_{n, i}$ and $b_{n, j}$ would not then share any non-zero boundary segment with the area $C$; contradicting (7).

Lemma (c) No two areas $b_{n, i}, b_{n, j}$ of $B_{n}$ can share a non-zero boundary segment that has no point in common with $C$ if each area of $B_{n}$ abuts the area $C$ only once.

Planar Map $\mathcal{C}$
(9) Moreover, if the region $A_{m}$ is empty, and each area of the region $B_{n}$ abuts the area $C$ only once, then no two areas of $B_{n}$-say $b_{n, 1}$ and $b_{n, 2}$ (see Fig.3) - can share a non-zero boundary that does not intersect $C$ :
(a) since that would divide $\left\{B_{n}-b_{n, 1}-b_{n, 2}\right\}$ into two non-empty regions, say $B_{n, \text { upper }}$ and $B_{n, \text { lower }}$;
(b) such that no area of the region $B_{n, \text { upper }}$ shares a non-zero boundary with any area of the region $B_{n, \text { lower }}$; whence:
(i) some areas in each of the regions $B_{n, \text { upper }}$ and $B_{n, \text { lower }}$ would necessarily require the 2 colours not shared with the areas $C, b_{n, 1}$ and $b_{n, 2}$; since:

- if one of the regions, say $B_{n, \text { upper }}$, requires only 1 of the 2 colours,
- then annexing one of the areas of $B_{n, \text { lower }}$, say $b_{n, \text { lower }}$, which has this colour, say $x$, into $C$ would reduce $\mathcal{C}$ identically to $\mathcal{M}$,
- whilst still requiring 5 colours (since $b_{n}$, lower would now abut areas with all the four colours of $\mathcal{M}$ ),
- thereby violating minimality;
(ii) whilst each of the regions $\left\{B_{n, \text { upper }}+b_{n, 1}+b_{n, 2}+C\right\}$ and $\left\{B_{n, \text { lower }}+b_{n, 1}+b_{n, 2}+C\right\}$ would necessarily require $C$ to have the $5^{\text {th }}$ colour-and violate minimality-in order to avoid violating minimality when combined (superimposed suitably) to form $\mathcal{C}$ !

Lemma (d) Some area $b_{n, i}$ of $B_{n}$ must share at least two, distinctly separated, non-zero, boundary segments with $C$

Planar Map $\mathcal{C}$
(10) Hence, if the region $A_{m}$ is empty, and each area of the region $B_{n}$ abuts the area $C$ only once, then all the areas of the region $B_{n}$ can be treated as bounded by longitudinals that meet at the orientation pole $N$ of the hemisphere (see Fig.4).
(11) However, the region $B_{n}$ would then require at most 2 colours if $n$ is even, and 3 colours if $n$ is odd; whence the area $C$ would not require a $5^{\text {th }}$ colour, contradicting minimality.

Lemma (e) No area $b_{n, k}$ of $B_{n}$ can share two, distinctly separated, non-zero boundary segments with the area $C$.
(12) Hence some area in the region $B_{n}$, say $b_{n, k}$, must abut the area $C$ at at least two, distinctly separated, non-zero boundary sections.
(13) However, the region $\left\{C+b_{n, k}\right\}$ can then be treated as an equatorial band which divides the areas in the region $\left\{B_{n}-b_{n, k}\right\}$ into the two regions $B_{L}$ (see Fig.5) and $B_{R}$ (not shown); such that no area of the region $B_{L}$ abuts any area of the region $B_{R}$.

(14) Hence the regions $\left\{C+b_{n, k}+B_{L}\right\}$ and $\left\{C+b_{n, k}+B_{R}\right\}$ can be treated as two, distinctly separated, hemispherical maps $\mathcal{C}_{L}$ and $\mathcal{C}_{R}$ :
(a) each of which has less than the number of areas required for minimality; but
(b) each of which necessarily requires a $5^{t h}$ colour;
thus contradicting the assumption that $\left\{A_{m}+B_{n}+C\right\}$ is a minimal configuration.
We conclude that no planar map requires more than 4 colours.
Concluding comment: In conclusion, we note that the above pre-formal proof of the Four Colour Theorem highlights the significance of differentiating between (see [An21], §5. What is knowledge?):

- Plato's knowledge as justified true belief, which seeks a formal proof in a first-order mathematical language in order to justify a belief as true; and
- Piccinini's knowledge as factually grounded belief, which seeks a pre-formal proof in order to justify the axioms and rules of inference of a first-order mathematical language which can, then, formally prove the belief as justifiably true under a well-defined interpretation of the language.
